In his discussion of veracity, Rashdall argues that “upon hedonistic assumptions the exceptions” to veracity “would be much more numerous . . . There would be no reason why we should resist that tendency to say (in matters of no importance), at any expense to Truth, what would be agreeable to the hearer.” His consequentialism, however, rejects this “minor lying,” as he explains in the following excerpt from *The Theory of Good and Evil*:

I believe that we do on reflection recognize something intrinsically fitting in the rule which prescribes that a rational being, endowed with faculties which enable him to pursue, to communicate, and to love the truth, should use those faculties in that way rather than for the purpose of making things appear otherwise than they are.

If reflection does not support harmless lying simply because it will increase the amount of pleasure in the world, reflection does not support an exceptionless rule against lying, either: “But, it is equally easy to show that to erect the principle of Veracity into a hard and fast rule admitting of no exceptions is out of harmony with the belief and the practice of most conscientious persons.” As examples of morally permitted exceptions, he states the following:

. . . deception practised by detectives, or by private persons towards a brigand inquiring about the whereabouts of his victim, or to the denial of bad news to sick persons, or to lies told for the preservation of important secrets, or to the employment of ancient formulae (a political oath, a declaration of faith imposed by some ancient Statute, or a confession of faith).

Such lies are morally permitted because they do not undermine veracity more generally:

Though they in some cases deceive for the moment the particular person to whom they are addressed, they do not to any important extent tend to weaken respect for truth, the habit of telling the truth, and the general confidence in other people’s statements.

Reflection morally permits these lies because “there are other goods besides truth-speaking and truth-loving.” He continues:

In each case we must decide which is of the greatest worth—the speaking of truth and the habit of speaking it which my lie would tend to discourage, or the life which my lie will save, the injustice that it will prevent, the practical good which it will enable me to do, the greater truth which it will enable me to diffuse.

Rashdall concludes that “even in the case of Veracity—the stronghold of popular Intuitionism—the case of an intuitively discerned rule of conduct, universally binding without any consideration of consequences” is not to be had. In place of an exceptionless rule against lying, morality consists in “reconciling the ‘intuitive’ basis of the virtue [of veracity] with the occurrence of exceptions based on consideration of consequences.”

### W. D. Ross

In *The Right and the Good* (1930), W. D. Ross (1877–1971) rejects both “the view of [Immanuel] Kant,” according to which there is a plurality of exceptionless perfect duties, all of which always take precedence over the plurality of imperfect duties, and “the view of . . . Professor Moore and Dr. Rashdall,” according to which is

only one exceptionless duty, namely, to produce the greatest amount of good.

Ross's position is that there is a plurality of irreducible self-evident basic moral "*prima facie* duties." These are the "perfect" duties of fidelity (keeping promises), of reparation (making amends), of gratitude, of justice (distributing goods according to merit), and of nonmaleficence (not harming others); and the "imperfect" duties of benevolence (helping others) and of self-improvement. These duties are *prima facie* because, although there is a ranking of these duties that is similar to that of Kant's distinction between perfect and imperfect duty, such that "perfect" *prima facie* duties take precedence over "imperfect" *prima facie* duties, all things being equal, perfect *prima facie* duties do not always take precedence over imperfect *prima facie* duties.

Sometimes, despite the greater stringency (in general) of a perfect *prima facie* duty over an imperfect *prima facie* duty, there can be an instance of fulfilling the perfect *prima facie* duty that is "trivial," and an instance of fulfilling the imperfect *prima facie* duty that is "serious." In such circumstances, one's "duty *sans phrase*," or actual or absolute duty, is to fulfill the imperfect *prima facie* duty, as he states in the following excerpt:

If I have promised to meet a friend at a particular time for some trivial purpose, I should certainly think myself justified in breaking my engagement if by doing so I could prevent a serious accident or bring relief to the victims of one.

Precisely how one weighs the typically more stringent duties with their serious and trivial instances against the typically less stringent duties with their serious and trivial instance is a matter of "perception."

Whenever there is a conflict between two or more *prima facie* duties in some instance, and one duty is judged to be the most salient, the other duties remain; the person feels a "compunction" at not fulfilling them and has a duty to make up for not fulfilling them, even if not fulfilling them is his or her actual duty in this instance: As Ross describes it:

If, as almost all moralists except Kant are agreed, and as most plain men think, it is sometimes right to tell a lie or to break a promise, it must be maintained that there is a difference between *prima facie* duty and actual or absolute duty. When we think ourselves justified in breaking, and indeed morally obliged to break, a promise in order to relieve some one's distress, we do not for a moment cease to recognize a *prima facie* duty to keep our promise, and this leads us to feel, not indeed shame or repentance, but certainly compunction, for behaving as we do; we recognize, further, that it is our duty to make up somehow to the promisee for the breaking of the promise.

Since the duty remains, it has been argued that Ross should have (following Rashdall) used "*pro tanto*" to qualify nonabsolute duty, instead of *prima facie*.

Ross does not hold that the perfect *prima facie* duty not to lie is a basic duty. Instead, he holds that the duty is derived from two other basic duties. The first is the perfect *prima facie* duty to keep promises. Whenever someone enters into a normal conversation or writes nonfiction, then he or she is implicitly promising that he or she is telling the truth and not lying:

. . . an implicit promise, such as the implicit undertaking not to tell lies which seems to be implied in the act of entering into conversation (at any rate by civilized men), or the writing of books that purport to be history and not fiction.

The second basic duty is the perfect *prima facie* of nonmaleficence. Lies typically harm those who believe them: "But even before the implicit undertaking to tell the truth was established I had a duty not to tell lies, since to tell lies is *prima facie* to do a positive injury to another person." Because of this, there remains a perfect *prima facie* not to lie even if an individual is in a situation in which he or she believes that the other person is breaking the implicit promise not to lie to them:

A man who has deceived me has destroyed what would have been the main reason for its being my duty to tell him the truth. But we

should probably hesitate to say that by his breach of the implicit understanding my duty to tell him the truth has been entirely destroyed . . . therefore while a person who has been deceived by another is justified in refusing to answer his questions, he is not justified in telling him lies.

Because of the perfect *prima facie* not to harm others, there remains a perfect *prima facie* not to lie even if an individual is in a situation in which he or she believes that there is no implicit promise not to lie, and the violation is less grave:

Yet that this [perfect *prima facie* not to harm others] forms only a small part of the stringency of the duty of truthfulness may be inferred from the leniency with which we should judge deceit, in a case in which no implicit undertaking to tell the truth has been established.

Because of the perfect *prima facie* duty to keep promises, Ross also holds, presumably, that there remains a perfect *prima facie* not to lie even if an individual is in a situation in which he or she believes that the other person will not be harmed by their lie, or will be benefitted by their lie.

Because the duty not to lie is a *prima facie* duty, it follows that there can be instances in which, despite the greater stringency (in general) of the perfect *prima facie* duty not to lie, a person's duty *sans phrase* is to lie, in order to fulfill an imperfect duty of beneficence. This can occur, presumably, when the lie is about something trivial and the harm of telling the lie is minor, but the benefit of telling the lie is considerable. However, it also seems that it can be one's duty *sans phrase* to lie in order to fulfill an imperfect duty of beneficence, even if the lie is about something important and the harm of telling the lie is major, when the benefit of telling the lie is enormous.

Finally, there may be instances in which there is no implicit promise not to lie, and no harm done by a lie. Such could be the case of lying in a game in which the objective is to tell a convincing lie on occasion in order to advance in the game. Here it would seem that the derived perfect *prima facie* duty not to lie would simply not apply, and there would be nothing morally wrong about lying.

### Gilbert Ryle and J. L. Austin

Another development in the analysis of lying and deception was made by Gilbert Ryle (1900–76) in *The Concept of Mind* (1949). In that work Ryle identified certain verbs as “performance-verbs” that “signify the occurrence not just of actions but of suitable or correct actions. They signify achievements.” As an example, Ryle offered “deceive.” Such performance-verbs “signify not merely that some performance has been gone through, but also that something has been brought off by the agent going through it. They are verbs of success.” To deceive someone is to succeed at bringing something off, namely, to succeed at engendering (or sustaining) a false belief in someone. By contrast, “lie” is not a success verb. To lie to someone is not necessarily to succeed at bringing something off. Someone can lie and can be disbelieved; this fact does not prevent the lie from being a lie. Lying, therefore, is not a type of deceiving. At most, lying is a type of attempting to deceive.

In lectures developed in the 1940s that were eventually delivered in 1955 and later published in 1962 as *How to Do Things With Words*, J. L. Austin (1911–60) made a contribution to the analysis of lying by distinguishing between lying and making false promises. Austin distinguishes between constative utterances, or utterances that may be appraised as true or false, such as assertions, and performative utterances, or utterances that may not be appraised as true or false. Promises are examples of performatives. Promises themselves cannot be said to be true or false. Promises can be said to be in bad faith (insincere), or in good faith (sincere), depending on whether there is an intention to keep the promise or not.

It follows that a false promise cannot be a lie, because a lie must be capable of being true or false: “His utterance is perhaps misleading, probably deceitful and doubtless wrong, but it is not a lie or a misstatement.” It is possible that, on the basis of an insincere promise, someone may be deceived about a person's intentions, however: “At most we might make out a case for saying that it implies or insinuates a falsehood or misstatement (to the effect that he does intend to do something): but that is a very different matter.”

## History of Deception: 1950 to the Present

Lying and deception grew in importance as topics in philosophy in the latter half of the 20th century. As Sissela Bok pointed out in her groundbreaking book *Lying: Moral Choice in Public and Private Life* (1978), the "major works of moral philosophy of this century . . . are silent on this subject" of "truth-telling and lying," and the eight-volume *Encyclopedia of Philosophy*, published in 1967, "contains not one reference to lying or to deception, much less an entire article devoted to such questions."

Bok contributed to the revival of interest in lying and deception in philosophy that occurred from 1977 to 1978. Parallel to this, the work of psychologist Paul Ekman on deception began appearing in the late 1960s and early 1970s. They inspired all psychologists writing on lying, including social psychologist Bella DePaulo in the 1990s, who engaged with Bok.

In the 1960s there had been some articles addressing these topics. Arnold Isenberg's article "Deontology and the Ethics of Lying" (1964) defended the following definition: "A lie is a statement made by one who does not believe it with the intention that someone else shall be led to believe it." According to this definition there are three necessary, and jointly sufficient, conditions for lying. The first is the statement condition, the condition that a statement is made. The second is a variation on the untruthfulness condition, the condition that the statement be believed to be false. The third is the intention to deceive condition, the condition that the liar intends that the dupe believe something false (here, the untruthful statement). Importantly, Isenberg rejected the falsity condition, the condition that the untruthful statement be false.

With this definition Isenberg attempted to limit the scope of lying, arguing that the statement in question may be too vague for the act to be called a lie; that the degree of belief and disbelief in the speaker can vary, and hence may preclude lying; and that the intention may be "strong or weak, definite or indefinite." The result of that final variation in intention is that an advertiser who boosted products, "knowing that everyone expects him to exaggerate," is "probably not to be called a liar." Isenberg also held that there is an awareness on the part of the liar of the "listener's mentality and cognitive situation," and that so-called polite lies, such as the words "*She is not at home*," delivered by a servant or relative at the door, are not lies at all, but merely euphemisms.

Frederick A. Siegler's most important article on the topic, "Lying," (1966), expanded upon the statement condition, arguing that the liar must be "conveying meaning through conventional signs," as opposed to natural signs (for example, faking a limp). Siegler also distinguished between lying and telling a lie. This led him to adopt two positions on the falsity condition: falsehood was not necessary for lying, but it was necessary for telling a lie.

However, Siegler's distinction between lying and telling a lie was rejected by subsequent writers, and Don Mannison argued that neither lying nor telling a lie required falsehood ("Lying and Lies," 1969). Mannison, drawing upon the speech act theory of J. L. Austin, added that an

act of lying is an illocutionary act and not a perlocutionary act, because, “The existence of an act of lying is not dependent upon the production of a particular response or state in an audience.” To use the terminology of Gilbert Ryle (*The Concept of Mind*, 1949), he argued that a “lie” is not a success verb. This makes “lie” importantly different from “deceive,” which is indeed a success verb and which Ryle included in his list of success verbs.

### Roderick M. Chisholm and Thomas D. Feehan

Roderick M. Chisholm and Thomas D. Feehan’s article “The Intent to Deceive” (1977) remains the most influential article from this period. This article addressed both deception and lying. Chisholm and Feehan argued that deception consisted in either deception by commission (doing) or deception by omission (allowing). The four types of deception by commission are contributing to the dupe’s acquiring a false belief, contributing to his or her continuing to hold a false belief, contributing to his or her ceasing to hold a true belief, and contributing to preventing him/her from acquiring a true belief.

The four types of deception by omission are allowing the dupe to acquire a false belief, allowing him/her to continue to hold a false belief, allowing him/her to cease to hold a true belief, and allowing him/her to continue without a true belief. This taxonomy of deception remains highly controversial, however. With respect to the four cases of negative deception, in which the person is made or allowed to lose a true belief or to fail to acquire a true belief but at no point has a false belief (as in the cases of positive deception), it has subsequently been argued that this is not a case of deception at all and is instead a matter of being kept in ignorance.

Perhaps the most important contribution that Chisholm and Feehan made was to argue that the statement condition and the intention to deceive condition be replaced by the assertion condition. In order to lie, it is necessary to make a statement. The statement-making has to be an assertion, however, because one can make a statement in play or irony. In the case of a liar (*L*), and an intended dupe (*D*), and a believed-false proposition (*p*), they say that the liar asserts *p*, and hence is lying, when: “*L* states *p* to *D* and does so under

conditions which, *L* believes, justify *D* in believing that he, *L*, not only accepts *p*, but also intends to contribute causally to *D*’s believing that he, *L*, accepts *p*.”

This account of lying has two implications, both of which are controversial. The first is that the liar only wishes the dupe to believe things about the liar’s beliefs and intentions and not necessarily to believe what the liar is saying. That is, the liar only necessarily wishes the recipient to believe that the liar is being honest, and that the liar is intending to be believed to be honest. The second implication is that if a person believes that the circumstances are such that the would-be dupe is not justified in believing that the speaker is being honest, then the person is not lying. For this reason, Chisholm and Feehan argue about an example taken from Immanuel Kant’s lectures that someone who is being mugged at knifepoint is not lying when he makes a false statement to the mugger, because the person cannot believe that the conditions are such that the mugger is justified in believing what he says. This means that the victim cannot make even a truthful assertion to the mugger about not having any money on her person. No assertion is possible.

Alan Donagan reached a similar conclusion about being unable to lie to aggressors in his *A Theory of Morality* (1977). He argued that lying must occur in conditions of free communication and must be between fully responsible and rational persons. Hence, it is not possible to lie to “children, madmen, or those whose minds have been impaired by age or illness,” and it is not possible to lie to “a would-be murderer who threatens your life if you will not tell him where his quarry has gone,” and in general to those who place you under duress, because in such circumstances your act of communication is not free.

Charles Fried, in the chapter titled “On Lying” in *Right and Wrong* (1978), argued, like Chisholm and Feehan, for an assertion condition for lying: “A person lies when he asserts a proposition he believes to be false.” To make an assertion, according to Fried, is to “give an assurance that the statement is true.” The institution of assertion is “that institution by which people, when they make statements to each other, invite belief, and not belief based on the evidence of the statement

so much as on the faith of the statement.” A lie, therefore, “invites belief” in something that the liar believes to be false. He rejected Chisholm and Feehan’s account of assertion as depending on whether the asserter believes that the circumstances justify belief in the asserter’s honesty.

### Why Lies are Morally Wrong

Many of these writers were also concerned with the moral question of why lies are morally wrong, and whether or not all lies are morally wrong. Isenberg considered the position of deontologists that in all lying there is an element of moral wrongness, which is constant. Even if there are circumstances in which lying is justified, lying is *pro tanto* wrong: the wrongness is overridden but not

removed. Isenberg agreed with the deontologists to the extent that although lies can be excused or justified, lies always stand in need of one or the other: “it is the normal thing to demand a reason for lying,” even if such a reason can be given.

On Chisholm and Feehan’s account of lies as untruthful assertions, “The liar would have his victim believe that, at the moment at least, the liar is someone in whom he may place his faith,” and hence the person who is lied to has had his or her right violated, because “*D* has the right to expect that *L* himself believes *p*.” Every lie is therefore a violation of a right. Because one cannot make an assertion to a mugger, the mugger has no such right to be violated.

Donagan’s narrow account of lying allowed him to argue for an absolute prohibition on all lying because making untruthful statements or assertions to those who, for example, threatened one, was not lying and was permitted. Fried, meanwhile, argued that a lie, which is always “a broken promise,” is wrong because it “violates the principle of respect, for I must affirm that the mind of another person is available to me in a way which I cannot agree my mind would be available to him.” Nevertheless, Fried thought that some lies were justified. In the case of a noninnocent who initiates an encounter (for example, asks one a question) and leaves one “with no choice but to lie or to yield a right,” such a noninnocent has “no right to the truth.” Lying to muggers and to would-be murderers is therefore justified lying.

### Sissela Bok

It was Bok, however, who approached the topics of lying and deception with a practical agenda. She did provide a definition of lying according to which a lie is “any intentionally deceptive message which is stated.” She thus rejected not only the falsity condition but also the untruthfulness condition. She reduced lying to any deception by means of a statement. Although Bok rejected the absolutist prohibition on lying, she defended a “principle of veracity,” according to which lies have an “initial negative weight.” Lying “requires explanation, whereas truth ordinarily does not.” Hence, there is always a “burden of proof” on the liar.

On this basis she argued for a three-step test for lies. First, a lie must be a “last resort.” In any situation in which a lie is a possible choice, one must

*Illusionist Riku Issakainen performs during Circus Festival 2010 in Kerava, Finland. This type of magic-show deception by consent is, according to psychologist Paul Ekman, generally distinguished from a lie, which is an intentional deception without prior notification. Ekman’s work on deception began appearing in the late 1960s and early 1970s.*

seek nonlying alternatives. Second, even when a lie is a last resort, all of the harms and benefits of the lie must be considered. Here Bok included not merely the harm to the dupe of the lie but also the harm done to the liar in terms of effort to cover up the lie and damage to credibility, and the damage to the overall level of trust in communication in society. Her point was that the liar was biased to underestimate the risk of discovery and overestimate the benefits of lying and to ignore the difference between lies that are truly isolated occurrences and lies that tend to become institutional practices. Third, in the light of all of these harms and benefits, the lie must be in principle justifiable if it were to be made public: “The test of publicity asks which lies, if any, would survive the appeal for justification to reasonable persons.” Her publicity test is based on the Golden Rule:

We must share the perspective of those affected by our choices, and ask how we would react if the lies we are contemplating were told to us. We must, then, adopt the perspective not only of liars but of all those lied to; and not only of particular persons but of all those affected by lies.

This three-step test allowed for an examination of many deceptive practices in society, including white lies, lies to children, lies to the sick and dying, paternalistic lies more generally, lies for the public good, lies in letters of recommendation, lies in social science research, and lies to protect clients and colleagues, as well as lies to liars and lies to enemies. Although lies told to would-be murderers to protect innocents, lies told to protect one’s life, and lies necessary to save groups against plague, invasion, or political or religious persecution can survive this test, few of the many lies told in society can survive this test.

### Writings on Lies Since the Late 1970s

Subsequent to 1977–78 there have been two broad developments in writing on lying and deception in philosophy. The first concerns the moral distinction between lying and being misled by truthful assertion (or paltering). Traditionally, those writing on lying have made a strict moral distinction between lying and being misled by truthful assertion. In the case of lying, Alasdair MacIntyre

argued that the responsibility for being deceived is entirely on the liar, whereas in the case of being misled, the dupe is in part responsible for making inferences to falsehoods; Chisholm and Feehan maintained there is a breach of faith in the case of lying, because the dupe has the right to expect truthfulness, whereas in the case of being misled, there is no breach of faith. Finally, according to Jonathan Adler, lying is a violation of a norm of conversation that truthfulness is more important with respect to what we say than what we otherwise convey.

However, recent writers have rejected this strict moral distinction and have argued that it is false that lying is morally worse than misleading by truthful assertion. In *Truth and Truthfulness: An Essay in Genealogy* (2002), Bernard Williams, who has also accused previous writers of fetishizing assertion, rejects this preference for mere misleading over lying. In *Lying, Misleading, and the Role of What is Said* (2012), Jennifer Saul has attacked all of the past moral justifications for preferring merely misleading over lying. Finally, Frederick Schauer and Richard Zeckhauser have argued that merely misleading, or paltering, presents almost all of the same harms as lying but is more difficult to identify, harder to penalize, and hence may present a greater problem to society than lying.

The second development concerns the intention-to-deceive condition for lying. Traditionally, those writing on lying divided into those who held that lying involves an intention to deceive another person, and those who held lying may lack any intention to deceive. In the 20th century this latter position was very much in the minority. The 21st century, however, has seen a spate of articles devoted to defending the possibility of nondeceptive lying, including Thomas L. Carson’s “The Definition of Lying” (2006), Roy Sorensen’s “Bald-Faced Lies! Lying Without The Intent to Deceive” (2007), Don Fallis’s “What Is Lying?” (2009), and Andreas Stokke’s “Lying and Asserting” (2013). According to these authors, putative examples of lies without any intention to deceive include those of a murder witness, scared for his life giving untruthful testimony on the stand with no intention to be believed by the jury, and a college student denying that he plagiarized a paper without any intention that the dean believe him

in order to avoid expulsion. These putative examples of lies have in turn been contested by J. E. Mahon (2008) and J. Lackey (2013). If lies can truly be divided up into deceptive and nondeceptive lies, it remains to be seen if arguments for the moral wrongfulness of lying can apply to nondeceptive lying, or if alternative arguments must be provided—if, indeed, there is anything morally wrong with nondeceptive lying.

### Writing on Lies in Psychology

In the late 1960s and early 1970s, psychologists Paul Ekman and Wallace V. Friesen—inspired in part by the important work of Erving Goffman on how people unconsciously act and present themselves in everyday social interactions—examined nonverbal behavior in the specific context of intentional deception. They concluded that certain body movements and “micro” facial expressions, which are signs of emotions that are being suppressed or repressed, are produced when people intentionally deceive. The ability to detect such nonverbal “leakage” of emotions can enable people to detect attempts at deception, but such ability is rare without special training. Individuals who demonstrated the rare talent to detect such leakage, and hence lies, without special training were christened “truth wizards.” Claims about the inability of most people to detect lies due to their inability to detect leakage have recently been challenged by writers, such as Timothy R. Levine, who argue that nonverbal leakage by liars is the exception rather than the rule and that people normally detect lies on the basis of other factors, including prior factual knowledge and access to physical evidence.

Ekman also distinguished between lies and deception more generally, arguing that to lie is to intentionally (attempt to) deceive without prior notification. Lying was thus distinguished from simple error as well as deception by consent (for example, deception by magicians and poker players), but lying did not require the use of language (for example, concealment lies), and it was possible to lie by deceptively telling the truth (palterers).

Subsequent writers on lying, such as Mark Frank, have attempted to distinguish between active deception, or unauthorized intentional deception (i.e., lying) as well as authorized intentional deception, and passive deception, or

unintentional deception (for example, camouflage), and to consider the question of whether animals can lie.

Other psychologists, such as Bella DePaulo and Deborah Kashy, have paid more attention to the topics of how often people lie, different types of lies (self-centered lies versus other-centered lies), what people lie about (feelings and opinions versus plans versus achievements versus reasons for behavior), and the differences between men’s lies and women’s lies. Such writers also addressed the topic of the morality of lying, considering the difference between “serious” lies and nonserious lies and the question of whether altruistic lies, and harmless self-serving lies are justifiable, which led them to consider the arguments of Bok against lying.

## Hitler, Adolf

Following the establishment of the National Socialism Movement and the ascendance of the Nazi Party in Germany in 1933, the name Adolf Hitler became irrevocably intertwined with the concept of lying. The environment within Germany was ripe for Hitler's utopian promises because the country was still reeling from its defeat in World War I, and its pride had been bruised by the punishment meted out in the Treaty of Versailles. Hitler's entire career was founded on the principle that lies were justified if they allowed him to achieve his ends. Calling on the enormous resources at his command, Hitler waged a lengthy campaign of deception designed to undermine trust in one's own government, raise questions about the reliability of allies, convince the world that Germany was invincible, and assure the German population that his end goal was utopia for the German people. Because the web of deception was so extensive, it became almost impossible to sort out fact from propaganda within a Germany controlled by Hitler and the Nazi Party.

Adolf Hitler was born in 1889 in Braunau in Upper Austria but became a German citizen. Throughout his public life he had been known for his anti-Semitic views. By 1921, he had been officially named chairman of the Nazi Party. Hitler laid out his plans to make Germany the dominant world power in *Mein Kampf* (*My Struggle*) in 1927. He expressed his views on lying clearly

in what became known as the Big Lie, stating that lies should be big and simple, and he maintained that people would begin to believe any lie that was repeated often enough. He devoted two chapters of the book to propaganda.

Almost immediately upon attaining power, Hitler set up the Ministry of Public Enlightenment and Propaganda and installed Joseph Goebbels as its head. The ministry was assigned to direct and monitor the activities of art, music, theater, films, books, radio, education, and the press. It was also charged with keeping foreign media out of the hands of the German public. The overriding goal was always to protect the image of Hitler and the Nazi Party so that the German people did not rise up in revolt. Anyone who threatened that image was likely to be hunted down by German storm troopers or the Gestapo.

Identifying his major external enemies as Great Britain and the Soviet Union, Hitler was willing to use any means at his disposal to bring those enemies down. In August 1939, the news that Germany and the Soviet Union had signed a non-aggression pact sent a ripple of surprise around the world. The pact paved the way for Hitler to proceed with his plans to invade Poland on September 1, 1939, while allowing him to keep quiet about the possibility that, despite the alliance, Germany would later invade the Soviet Union. The invasion of Poland was allegedly justified by perceived mistreatment of Germans living in Poland. Records made available after Germany's fall have made it clear that by 1941, plans for the invasion of the Soviet Union were already underway. That invasion was timed to coincide with mass extermination of European Jews.

### **Campaign Against the Jews**

On the night of November 9, 1938, German storm troopers and Nazi officials blazed across Germany, Austria, and parts of Czechoslovakia in what became known as the Kristallnacht (Night of Broken Glass). The goal was to remove Jews from their homes and strip them of their property. In January 1939, Hitler delivered an address to top Nazi officials in which he proclaimed that European Jews were planning to wage war against Germany and informed party members that the Jews were responsible for Great Britain's defiance of Germany.

In January 1941, Hitler announced to Nazis attending the Wannsee Conference that he was instituting plans to engage in the widespread extermination of Jews. Euphemistically referred to as the Final Solution, the extermination plan was the culmination of a campaign that had begun in 1933 when Hitler rose to power. After experiencing almost a decade of anti-Semitic propaganda and legal discrimination against Jews, many Germans were willing to blame Jews rather than Hitler and the Nazis for all problems. The isolation of Jews into ghettos was seen as justifiable because of the success of Nazi propagandists in convincing Germans that Jews spread disease.

Within Germany, Hitler and the Nazi Party targeted any individual or group deemed to have potential for interfering with the goals of German domination and the creation of the perfect Aryan race. The chief target continued to be the Jewish people, and Hitler used his web of deception to convince other Germans that Jews were their enemies, warning them that Jews were bent on world domination. Over the course of the war, some six million European Jews were exterminated by the German war machine. In addition to the Jews, Hitler sought to eradicate the very existence of homosexuals, the handicapped, the Roma (Gypsy) population, Catholics, Poles, and Czechs. The last two groups were targeted because Germany had been forced to concede land to Poland and Czechoslovakia at the end of World War I.

In 1939, Hitler orchestrated the passage of the Special Wartime Penal Code, which gave judges the power to arbitrarily increase sentences of anyone deemed to be undermining Germany's war effort. The predictable result was that few people were willing to challenge the Nazis openly. Nevertheless, there were some individuals brave enough to risk exposure. One such individual was Otto Hampel, a factory worker who engaged in a campaign to distribute postcards in public places, informing other Germans of the truth behind Hitler's deceptions. He was betrayed by an informant, and he and his wife were executed in March 1943. It was not until 2009 that Hampel's story, which had been told in 1947 by Hans Fallada in *Every Man Dies Alone*, was translated into English for the first time.

By the spring of 1939, it had already become clear that the United States would be affected by

the gathering war clouds in a number of ways, despite its ostensible neutrality. Oswald Garrison Villard reported in his regular column for *The Nation* that travelers returning to the United States from Germany were contending that maintaining business relations with Hitler's Germany had become virtually impossible because contracts were being broken regularly. He noted that falsehoods and chicanery were the order of the day because serving German self-interests dominated all business dealings, and he announced that force was being used to achieve Hitler's goals. Villard also reported that "wholesale plundering of Jews" was underway and stated that Hitler was well on the way to raising a generation of children that were convinced that "might makes right."

Throughout World War II, one of Hitler's favorite tactics was exaggerating Allied losses and under-reporting those of his own forces. In August 1941, for instance, during the German invasion of the Soviet Union, official German reports stated that Germany had captured 895,000 enemy soldiers in addition to killing or wounding hundreds of thousands more. The reports also claimed that Germany had commandeered 13,145 enemy tanks, 10,388 pieces of artillery, and 9,082 aircraft. The Soviet government announced that these figures were comparable to an "Arabian fairy tale," insisting that their own losses were accurately recorded as 600,000 casualties, 5,000 tanks, 7,000 guns, and 4,000 planes.

Hitler also employed the tactic of using word-of-mouth propaganda to heighten Germany's reputation of invincibility. In France, he employed professional mourners who showed up in public places bemoaning the heavy losses to France. Other tactics involved using fortune-tellers to predict an ultimate German victory and spreading rumors of secret German weapons.

In "Divide and Conquer," a pamphlet put out in 1942 by the U.S. Office of Facts and Figures, the U.S. government attempted to educate the American public about Hitler's propaganda tactics. The pamphlet stated that Hitler's lies involved assurances that democracy was at risk, that the American military was incapable of standing up to Germany, that the Allies had already lost the war in the Pacific, that the American West Coast was extremely vulnerable to enemy attack, that

the British were decadent, and that war would bankrupt the United States.

In April 1945, Hitler secretly married his long-term mistress Eva Braun. Well aware that the end was near and that he would be called to account for his crimes and deceptions, on April 30, 1945, the pair committed suicide in an underground bunker.

## Hockey

Ice hockey is a competitive team sport in which opposing teams try to score on each other; a point is scored when a team advances the puck into the opponent's goal. Teams rely on physical traits, such as strength, agility, and fitness; on cognitive traits, such as intellect, planning, and creativity; on spatial-temporal reasoning; and on strategies to attack and defend collaboratively. Alongside

these assets are tactics such as the deke, diving, and vaguely handled interviews, each of which uses deception by presenting misleading information during or between games. These tactics are encoded in the lexicon of the game, and each has an analog in other competitive team sports.

### Deke

When facing a defender, a common tool of the puck-handler is the deke—a feigned motion of the body and arms intended to trick the defender into believing the puck-handler will move in a specific direction. If the defender is successfully tricked by the deke, he will commit his own momentum in the direction of the deke, away from the actual intended direction of the skater.

For example, a puck-handler who dekes left (that is, to the defender's right) performs the deke with a combination of body gestures, including turning his legs and skates, dropping one shoulder, and moving the stick and puck leftward. Should the defender believe the deke, he will move toward the puck-carrier's left, opening up space for the puck-carrier to proceed forward on the right.

The puck-handler may also be said to deke a goaltender by feigning a particular type of shot but moving to a different stroke before actually releasing the puck. For example, the puck-carrier may do a forehand-to-backhand deke—act as if he is about to shoot forehand, with his shooting hand (lower on the stick shaft) out to his side and the puck resting on the forward (concave) face of the stick blade. The goaltender may see this and commit himself to position against a forehand shot. The puck-handler can then deke by pulling the puck with his stick across the ice in front of himself to the opposite side of his body. He is now set for a backhand shot, with his shooting hand ahead of his body and the puck resting against the back (convex) face of the stick blade.

There is no analogous term for a feint made by the goaltender, but the goaltender may fake a shooter out in a similar fashion—by exposing one part of the goal, tempting the shooter to aim for that target, and quickly closing off the exposed area as the attacker handler shoots the puck.

The word *deke* is of Canadian-English origin, used as a noun or a verb, and is short for “decoy.” It is also used in other nations in the context of

ice hockey. Its association with a specialized lexical item indicates the extent to which this deceptive move is intrinsic to the skill set of the hockey player. Canadians use the term for similar acts in other sports, such as American or association football; elsewhere, the concept in other sports is expressed in different terms, such as “juke” in basketball or “fake” in American football.

### Diving

Another deceptive practice within hockey is diving, an action in which a player pretends to be hurt or illegally hit in an attempt to draw a penalty against the opposing team. Like other team sports, ice hockey has a set of rules that can be considered a code of behavior, and violations result in penalties assessed by the game referee against an individual or a team. Although some degree of physical contact between opponents is allowable, certain types of contact are explicitly disallowed. Such infractions result in the penalized player being sent off the ice, in most cases for two or five minutes. While serving the penalty, the violator's team plays with one fewer player, a scenario called a “power play” for the team with the one-man advantage.

Given the advantage that results from power-play situations, there is some motivation to make an opponent appear to have committed an infraction in order to receive a power play as a benefit. A player may fall as if tripped, or pretend to be hit illegally by an elbow, with the intent of having the referee call a penalty on the opposing player. Diving comprises these sorts of embellished behaviors and is certainly not unique to hockey; association football players also dive to incur penalties against opponents. Similar behavior occurs in basketball, where it is called “flopping.”

Diving as a strategy is not held in high regard in hockey, in contrast with other behavior that is technically against the rules but is tolerated and cheered. Ironically, diving itself is punishable, so that a player who is truly illegally hit but who also embellishes the effects ends up serving an offsetting penalty at the same time as his opponent, with neither team receiving a power play as a result. Thus, the behavior is salient enough that it is encoded within the rules of the game: There is a specific clause in the official rulebooks

of international and National Hockey League (NHL) hockey that forbids this behavior, and there is a standardized hand signal that the referee uses to indicate the call.

### Deception in Media Interviews

Another type of deceptive practice in hockey arises in interviews and press conferences, in which professional players or coaches respond to questions from journalists. These interviews often address strategies and mental states of the team before, during, and after a game. Interviewees typically maintain a relatively neutral stance by avoiding extremely positive or negative evaluations in their responses. Moreover, interviewees tend to avoid sharing too much strategy in order to ensure that upcoming opponents cannot use such information to aid their preparation.

A specific instance of this appears in how teams report injuries among their players. If a team member is unable to play, the team must explain the reasons for his absence to its fan base. Because of the physical nature of the sport, however, teams sometimes provide only minimal detail in order to prevent opposing teams from targeting players with recent injuries. Teams thus often report injuries in the vaguest possible terms, such as upper- or lower-body injuries. For example, if a player misses a game because of a knee injury, the team might only report it as a lower-body injury, for fear that a more honest report would invite opponents to target the player's still-healing knee upon his return.

The act of minimizing detail about strategy and injury presents a certain level of masking of truthful information by hedging and relatively vague responses. This behavior is not unique to interviews with hockey players and coaches; it arises in many professional sports.

While behaviors such as diving, dekes, and vague interviews do not involve directly false statements, all of them are deceptive in how they mask relevant details or falsely suggest through gesture that some action has taken place.

## Honest Baseline Behaviors

When changes in behavior are the goal, either in the course of scientific research or in practice, accurate measurement of behavior is critical. A behavioral change is the difference between ongoing behavior in its normal, natural state and behavior following an intervention. In psychological research and practice, the behavior in the normal, natural state is called the baseline, while behavior following an intervention may be called treatment or experimental. While the reasons why accuracy is important for measuring behavior following an intervention are somewhat obvious—for example, to see if the intervention is effective—the accuracy of baseline measurements is equally, if not more, important.

In addition to serving as a starting point against which to measure behavioral changes after a manipulation, baseline measures are also used to determine whether or not an intervention is necessary. In clinical practice, baseline measures are used to determine treatment plans; for example, the frequency and amount of drug use partially informs the decision of whether inpatient or outpatient treatment is warranted. Inaccurate baseline measures may result in inadequate or unnecessary treatment of psychological problems.

Similarly, baseline behaviors can inform managers in business settings whether or not changes in working conditions are necessary. Inaccurate baseline measures in such situations could result in unnecessary or insufficient changes in processes. In all three cases—research, clinical practice, and making business decisions—the

assumption that behavior measured at baseline is an accurate representation of what an individual would normally do lies at the heart of any assessment of behavioral change. Identifying situations where an individual is likely to provide dishonest baseline behaviors and employing strategies to prevent such deception are critical for sound behavioral modification.

Baseline behavior is typically stable and predictable in the absence of manipulations. It is possible, however, for deviations in the baseline to occur. Deviations from a stable baseline—in the absence of manipulation—may indicate deception. Abrupt changes in behavior are unlikely to happen in the absence of an intervening event. Identifying these unlikely behaviors allows researchers to examine if the behaviors are deceitful. Thus, detecting deviations from the stable baseline can be utilized as a potential deception detection strategy. Additional threats to honest baseline measures, such as demand characteristics and observation effects, are also possible.

### **Demand Characteristics**

A common cause of dishonest baseline behaviors arises from the individual being aware of the reasons why his or her behavior is being measured. Often called demand characteristics, the individual's perception of the reasons for observation result in unconscious or unintentional alterations in behavior. Demand characteristics can manifest changes in baseline behavior in several ways and are often called the "good participant," the "bad participant," and the "apprehensive participant."

A "good participant" is an individual who behaves such that his or her perception of the experimenter's hypothesis is confirmed. This is not to be confused with the "faithful participant," one who exhibits honest baseline behavior. The "good participant" can cause an overestimation of a treatment effect by producing extreme baseline and treatment data, as the participant's behavior was partially controlled by his or her expectation. For example, a person participating in a study that is supposed to boost memory may feign poor baseline memory so that his or her memory is significantly higher (by comparison) in the treatment trials.

Alternatively, the individual may behave the opposite of his or her perception of a "good

participant" and instead act as a "bad participant" (sometimes referred to as a "negativistic participant"). Such participants provide inconsistent or contradictory data, which can result in underestimation of a treatment's effect. For instance, an assembly line worker who is reluctant to change practices may exhibit atypically high production during baseline measurements in order to prevent workflow changes from being initiated.

Finally, an individual's perception of the social implications of the behaviors being observed may result in the individual acting in a socially acceptable manner that is not indicative of his or her normal behavior; these people are known as "apprehensive participants." This type of inaccurate baseline behavior arises when the behavior being measured is either illegal, unethical, or deeply personal. Such behaviors include drug use, criminal activity, and sexual behavior. For example, college students tend to over-report alcohol consumption, as such consumption can be socially reinforced in the college environment. Alternatively, sexual behaviors—particularly deviant sexual behaviors—are sometimes under-reported, as social stigma is associated with these behaviors.

Many instruments used to measure such questionable behaviors include instructions for alleviating these concerns. Overall, demand characteristics are usually influenced simply by the participants' attitudes toward the experimenter (for example, participants who like the experimenter are more likely to act as "good participants"). All three types of demand characteristics can be minimized by the actions of the observer.

### **Observation Effects**

Sometimes inaccurate baseline data are gathered merely because the participants are aware that they are being observed. Such observation effects were most famously noted beginning in the 1950s in a long series of studies of worker productivity in a factory called the Hawthorne Works. Over the course of five years, numerous interventions were conducted to change worker productivity. No matter what the change was, from providing food and extra breaks throughout shifts to minute changes in lighting, production increased whenever the participants were made aware that they

*College students tend to over-report alcohol consumption, which can be socially reinforced in the college environment. This is an example of an “apprehensive participant,” someone who perceives the social implications of their observed behaviors, causing them to act in a more socially acceptable manner that is not indicative of their normal behavior.*

were being observed. Empirical support for what has been dubbed the Hawthorne effect has been found in medical and psychological research. For instance, mere observations of medical professionals increase their frequency of antibiotic prescribing, paramedic medication documentation, and antiseptic hand rub use. However, further studies have refuted the specific claims surrounding the Hawthorne effect.

Generally, the good participant and bad participant demand characteristics can be avoided by preventing participants from becoming aware of

research hypotheses. Although regulations requiring informed consent require at least some disclosure of study details, the reasons why observation is being conducted may usually be omitted or disguised. These designs may be referred to as “blind experiments” because the participants are unaware of—or blind to—certain aspects of the study. Akin to providing minimal details of the research, these two demand characteristics can be avoided by minimizing interaction between the observer and participant. Minimizing interaction prevents the formation of interpersonal relationships that could contribute to dishonest behavior and minimizes accidental disclosure of research hypotheses by the observer.

Deception on the part of the observer can also prevent demand characteristics by misleading or misdirecting participants’ perceptions of research hypotheses. This tactic is less appealing, as it can create further demand characteristics and is of questionable ethicality. If demand characteristics cannot be avoided by careful design, additional data can be gathered about the participants’ perceptions of the research hypothesis. Statistical procedures can also be used to evaluate whether demand characteristics were present and the extent to which they affected the data.

Other methods for collecting participant responses may be utilized if they provide a means for assessing behavior that cannot be feigned. For instance, psychologists may test cortisol levels (the stress hormone) in participants’ saliva along with recording written responses on questionnaires designed to measure stress. Although the responses on the questionnaire can easily be faked, rises in cortisol levels cannot.

The effects of observation on baseline behavior are similar to deception for social acceptance; they involve an artificial correction of behavior to a perceived appropriate level. The same strategies for avoiding inaccurate baseline data can be applied to both. To avoid observation effects or socially motivated dishonesty, observation should be as unobtrusive as possible. The use of technology, such as audio recording, video recording, or measurement devices built into equipment that automatically collect data, can be a means to unobtrusive observation. Care must be taken not to violate regulations of informed consent or other related laws. Although experimenter

deception (for example, lying about hypotheses, withholding information regarding the true nature of the study, or using unobtrusive means of measurement unbeknownst to the participants) may be necessary to eliminate dishonest baseline behavior, it must be kept as minimal as possible.

example, George Washington's admission that he cut down the cherry tree was an honest statement. An honest action is one that adheres to the trust conditions within a relationship; for example, Abe Lincoln was honest when he walked miles to return a few pennies. An honest person is one who regularly makes honest statements and performs honest actions.

Typically, honesty is only attributed where the speaker or actor might have been motivated to do otherwise. Thus, a man is seldom credited with honesty for shouting "Bingo!" in the church basement, even if he has a winning card. The term is used instead to honor those true statements that are made at the risk of loss, because that is when truth-telling is challenged. This is equally true for honest actions. A cashier will not regard a man's action particularly honest if he takes \$20 from the tip jar because he was short changed. On the other hand, should he set \$20 on the counter because he was given too much change, the cashier would justifiably regard this an honest action.

Honesty is deeply rooted in fellowship, such as marriage, friendship, and group affiliation, and facilitates two fundamental human needs: (1) the practical need to participate in equitable productive units (e.g., the family, which produces a home, an income, children, and so forth) and (2) the need for a sense of mutual belonging with others. Dishonesty in such relationships can wreck both of these human expectations. Marital infidelity, as a dishonest act, for example, destroys the felt sense of mutual belonging and often leads to the destruction of the economic structure as well.

Where groups increase in complexity and fellowship diminishes, such as in the movement from community to society, competitive and adversarial forces become a common feature of the interactive fabric; consequently, the collective exists in a form of cooperative competition in which honesty is an occasional and strategic resource. The communitarian vision of Amitai Etzioni, the civil religion of Robert Bellah and his student Jeffrey Alexander, and the discursive rationality of Jurgen Habermas can all be understood as modest proposals for an alternative social order, grounded in honesty, communitarian rationality, and integrity.

## Honesty

Honesty is a quality that can be shown in statements, actions, and persons. An honest statement is one that deliberately reveals a truth; for

### Honesty as a Value and a Virtue

Through honestly reporting to each other, collaborators can expand their intellectual and creative power dramatically with respect to planning, imagining, building, and so forth. Consider the following statements, for example:

- “Vegetables at Pete’s Market are half the price of the chain stores.”
- “Traffic on Highway 70 will be delayed by an hour.”
- “The boss likes all reports submitted in duplicate.”
- “I’ll pick up the children from the mall at 3:00.”
- “Your fiancé has been cheating on you.”

Where these statements are spoken honestly, they may: (1) save the listener money, (2) save the listener time, (3) give the listener an advantage at work, (4) protect the listener’s children, and (5) keep the listener from making a horrible mistake. Correlatively, where the statements are not honest, they may take these things away.

By freely choosing to set before others what is the case, the truth-teller allows the listener to take up a rightful position in what will happen next. In engineering, for example, the delivery of materials of a grade lower than specified is a dishonest action that subverts the prior deliberations of the engineers, possibly leading to great loss of property and life. Honest statements from the manufacturer might thus prevent catastrophe because they would reintroduce the engineers’ judgment into the equation. It is for such reasons that the honest manufacturer is valuable to both the engineer and the end users, a practical illustration of why honesty is referred to as a value.

By the same token, the manufacturer cannot fill an order for 700 tons of “Grade A” steel if the plant only has “Grade B,” which could mean real economic loss to the plant. For the purpose of illustration, with the elimination of any chance of being caught, the manufacturer must weigh two values: the value of profit and the value of being honest. This is the other sense in which honesty is a value: As a quality of character possessed by persons, the belief that one is honest adds weight to the sense of self-worth, and this weight functions

as a restraint against a pure will to deceive for advantage.

For reasons such as these, honesty is an honoring term. This makes etymological sense as well, for honesty and honor come from the root word *honos*. Persons possessing honesty are said to possess a virtue, which comes from the Latin word *virtus*, meaning strength. It regularly appears in Jane Austen novels, for example, where the female protagonist prefers a man of virtue to a man of power or wealth because virtue itself was regarded as a power, a strength of character that could facilitate the building of stable relationship.

Even today most people value honesty. Perhaps the strongest evidence of this is that liars must pretend they are honest in order to ply their trade.

Where honesty is attributed as a characteristic, the identified person is honored with a title of significant social worth. People identified as honest can expect a variety of positive outcomes: (1) their statements, even the ones that seem dubious, will be taken as sincere if not accurate; (2) their views will be given high valence in contesting (he said/she said) situations; and (3) they will be comparatively attractive to others as friends, co-workers, and employees. To be given the identity of an honest person is, thus, to be given a form of social capital.

Aristotle’s notion that virtues are cultivated as habits (*habitus*) is important to those interested in honesty. His claim suggests that failure to practice honesty makes honesty harder to practice, and the corollary.

### The Limits of Honesty

Even in intimate relationships, honesty is reasonably set aside at times, for while it is a virtue and a value, honesty has its limits. The only people more obnoxious than the ones who claim they are completely honest are the ones who actually are, as some honest statements are more properly regarded as brags, insults, fearmongerings, or cruelties. Virtuous honesty is, consequently, governed by Aristotle’s notion of the golden mean, and good judgment is required to exercise it properly.

Alongside questions of etiquette, decency, and compassion, there are other factors that limit honesty as well. For example, while one rightfully expects teammates to be honest with each other

when establishing strategy, no opponent expects or provides the same transparency. Many card games and competitive sports would be impossible if honesty were universal.

Honesty may also be withheld where conflict is experienced, especially under circumstances where profound loss is possible. Before leaving Germany, for example, Sigmund Freud was required to sign a document saying he had been well treated by the Nazis. Freud paused but a moment, then wrote “I heartily recommend the Gestapo to anyone,” and signed his name. Such prudence might easily find itself misused, overused, or abused, however. For example, a democratic society requires political honesty if citizens are to exercise their franchise. Within contemporary democracies, government deception and political misrepresentation may be characterized by practitioners as both prudent and necessary; nevertheless, such activities portend a shifting of the political forum away from the democratic (*demos* meaning people) and in the direction of the autocratic.

The performance of honesty may also be limited by aspects of human nature other than the will to exploit others. Human beings are not constant rational actors; they regularly speak untruths impulsively under momentary stresses and strains. A daughter, for example, may shout “I hate you!” at her mother—usually, such a statement should not be assessed on an honesty/dishonesty continuum. People are also uncertain with respect to mood states and feelings in general. Thus, a man may tell his doctor that he does not feel any work-related anxiety, a report that could be based more on unawareness than dishonesty. The limits of his honesty, in such a case, are the limits of his insight.

Rhetorical devices allow language to occur in strange places, with respect to honesty/dishonesty. One boy can say to another, “Cool sneakers,” and mean the opposite, and the other boy can know it. Honesty is not limited to literalness in speech.

### Managing Honesty Failures

Both when evaluating honesty failures and when pleading one’s case for an honesty failure, it is important to distinguish the honesty failure from a will to deceive or, where that is impossible, from a will to exploit.

Speech acts can be given in the spirit of honesty, even though they lack the qualities necessary to be characterized, in the end, as honest. Where that occurs, the speaker may repair the discursive violation through a common recalibrating device pointed out by Wittgenstein, which can be called the “I thought I” statement: “I thought I knew,” “I thought I felt,” “I thought I saw.” Through the “I thought I” locution, speakers rebrand their original (and ultimately inaccurate or untrue) statements as forgivable errors, even if they had adamantly denied at earlier points that a possibility of error existed. When the “I thought I . . .” locution is effective, the supplicant dissociates the honesty failure from any will to deceive; a technical error is admitted in order to remain morally unblemished. It is for this reason that when the executive branch of the federal government failed to provide evidence of weapons of mass destruction in Iraq, it gracefully moved to the “I thought I” locution.

Where the “I thought I” locution cannot be instigated, honesty failures cannot fully elide the charge that they were motivated by a will to deceive. All the same, a full charge of malicious will can be avoided by rebranding the questionable statements, calling them compulsions brought on by mood swings. Thus, a marital partner may disqualify a charge of dishonesty by explaining some previous claim with the simple words, “I was upset.”

One might also explain an honesty failure by saying “I was afraid.” In such cases, moral weakness is admitted as a means of avoiding a charge of moral corruption.

The fact that people regularly accommodate failures in honesty, converting those failures into errors and mood-driven accidents, suggests the prevalence of honesty failures. By accommodating honesty failures, confederates preserve a host of relationships that can be no more perfect than the people who belong to them.

## Humor

There are many different definitions of humor, but scholars who study humor have largely converged on the idea that humor involves the communication of multiple, incongruous meanings that are amusing in some manner. Humor is often associated with positive reactions like laughter and serves a variety of positive psychological and relational functions, such as coping with stress, increasing group cohesion, or helping to alleviate conflict. Humor can also serve negative functions when it is used to tease, humiliate, or deride another.

Several typologies of humor have tried to classify humor by its various forms, some of which classify humor as either positive or negative. More

complex taxonomies organize humor into over 20 types that speak to the form, function, and content of the humor. For example "telling funny stories" is distinguished from "unplanned humor," that is, spontaneous and naturally occurring. Certain types of humor clearly involve more deception than others. For example, comedians often tell a fictional anecdote but frame it as if it was something that really happened to them. Political cartoonists will often exaggerate the physical attributes of a famous person to make him or her instantly recognizable to the audience as well as invoke humor. Hoaxes, pranks, and even surprise parties involve both deception and humor to the extent they are designed to amuse but involve deceiving the target of the prank about the true nature of events.

### Humor and Deception

Humor is often associated with deception because it is based on incongruity. The work of D. E. Berlyne and others on incongruity theory and incongruity-resolution theory assumes that a surprise or contradiction is essential for humor. The theories assume a two-phase process in which the perceived incongruity must first be recognized and then accurately interpreted by the receiver in order for humor to be interpreted as funny. When people recognize and resolve the incongruity, they can understand a communication as humorous. One example of this is the use of sarcasm. Sarcasm involves using verbal and nonverbal cues that are incongruous with one another; for example, when someone says "great" while rolling his or her eyes and using a tone of voice that implies they mean the opposite.

Understanding sarcasm requires the understanding not only of the speaker's utterance but also the speaker's intent. The ability to presume another person's beliefs, feelings, intentions, or goals is termed *theory of mind*. Children often have a difficult time determining whether a statement that is contradictory to the facts is truthful (but wrong), sarcastic, or deceptive. Young children often accept the statement as sincere, whereas older children will assume that sarcastic comments are deceptive but may not understand the humor behind them. Even adults sometimes misunderstand sarcastic comments, especially if the joke is delivered through mediated channels.

Deception is a necessary part of most types of humor, especially sarcasm because of the incongruity between a speaker's statement and his or her intent.

However, humor is not always benign when associated with deception. Humor can be used to mask deceptive claims because it detracts attention from the content of the message and also generates feelings of well-being that cause the claims to be viewed positively, even if they are known to be untrue. Advertising that uses humor has been shown to be more effective than nonhumorous advertising, even when the audience knows the claims are false. Hoaxes, pranks, and cons are also examples of humor being used deceptively to trick others. Sometimes the purpose is to steal from or hurt others, but often the purpose is to gain notoriety, or simply to gain enjoyment out of fooling others.

One of the most famous hoaxes is the grainy photograph of the Loch Ness Monster taken in 1934 by Dr. Robert Wilson and known as the "surgeon's photograph." Wilson and his friend Marmaduke Wetherell later admitted to staging the photo, using a fake monster head attached to an 18-inch-long toy submarine, but the idea of the mysterious monster caught on, and many reputable scientists have spent considerable time and money trying to prove or disprove the existence of Nessie. Other hoaxes, such as the crop circles found in the English countryside starting in the 1970s and the 1995 Alien Autopsy video shown on the Fox Network and later circulated around the world, have garnered persistent believers even after the hoaxers admit to their fakery.

### Humor as a Mask

Humor can also be used to mask embarrassing or hurtful statements in interpersonal conflicts. Penelope Brown and Stephen Levinson's politeness theory explains why it is difficult to be honest with a close relationship partner or family member when discussing embarrassing, sensitive, or hurtful topics. The ambiguity inherent in humor makes it a likely tool for obfuscating the truth about such topics. Research has found that lies may be told for a variety of reasons, including to avoid punishment and blame, to make oneself more desirable, to protect one's privacy, to attain one's own goals, to avoid conflict, to protect the

feelings of another, and to build or maintain the self-esteem of self or other.

Humor may be used in pursuit of any of these deceptive motivations to make them more believable or more palatable to one's partners. Research has suggested that one of the benefits of using humor to achieve these goals is the fact that an individual can always retract it. If individuals say something hurtful or damaging to another, or if they are caught in a lie, they can always claim they were "only joking." The ambiguity of humor adds to the complexity of discovering when someone's relationship partners are telling him or her the complete truth.

Is deception delivered humorously more difficult to detect? Because humor and laughter are used to release tension, it is reasonable to expect that under the strain of an interrogation both truth-tellers and deceivers might use laughter and humor to relieve stress and make their audience more comfortable or to turn the interview toward more friendly topics. Little empirical research has addressed this issue specifically, but because deception is very difficult to detect in the heat of the moment even under the most optimal circumstances, the ambiguity associated with humor might cloud a detector's ability to accurately distinguish truth from deception. As described above, humor could be used to mask the intent behind a message or to retract a statement if the lie is detected by saying, "I was only joking." It is likely that humor will make deception more difficult to detect, but more empirical study is needed.

## Iago (Shakespeare's *Othello*)

Iago is a central character in William Shakespeare's *Othello, the Moor of Venice* (written ca.1603–04): He is a high-ranking soldier in the Venetian army—Othello's "ensign" or standard-bearer—who manipulates various characters with dire consequences. He is generally regarded as the antagonist of his superior, Othello, although the scope of his malevolent subterfuge, within the complex plot structure of the play, extends far beyond this.

### The Plot of *Othello*

The drama opens with Iago exploiting the angry resentment of Roderigo, a wealthy bachelor in love with the well-born Venetian lady Desdemona, newly and secretly married to Othello. Roderigo had unsuccessfully sought her hand in marriage, and Iago contrives to stir ill feeling between him and Desdemona's new husband. The initial cause of Iago's own particular animus against Othello appears twofold. He expresses anger at Othello for promoting Cassio (a younger fellow officer) above him and also claims that Othello has been sleeping with his wife, Emilia.

The removal of the central players at this juncture from Venice to Cyprus, where the Venetian

military has been detailed to repel a Turkish attack, provides Iago with an open field of opportunity to indulge further and fully his zeal for disruption. His machinations begin in earnest when he drives a wedge between Roderigo and Cassio. During the celebrations arranged when the Turkish fleet is scuppered in a storm offshore, Iago persuades Roderigo and a drunken Cassio (whom he has been deliberately plying with alcohol) to brawl: Cassio is held responsible by Othello and is demoted.

Next, Iago sets out to make Othello jealous by having him believe that his wife, Desdemona has been unfaithful with Cassio. To this end Iago convinces Emilia to steal a dropped handkerchief that had been given to Desdemona by Othello. Iago plants it in Cassio's room and has Othello watch as Iago, sowing seeds of jealousy, interrogates Cassio about the handkerchief. Cassio is having an affair with a prostitute, Bianca, and utters her name. But he speaks indistinctly, and Othello falls into the trap of believing that Cassio is actually talking about Desdemona. Furthermore, Othello overhears Bianca herself blaming Cassio for giving her a secondhand gift. As Iago had planned, Othello is now convinced of his wife's guilt and Cassio's betrayal. Enraged, he strikes the distraught and uncomprehending Desdemona and asks Iago to kill Cassio.

Iago's malicious campaign of slur and rumor has been working well so far. His next move is

to convince Roderigo to kill Cassio. Iago assures Roderigo that this needs to happen because Cassio has been appointed governor of Cyprus: If Cassio takes up that position, Othello and his wife will leave the island and return to Venice, frustrating Roderigo's designs on Desdemona. Roderigo duly assaults Cassio in the street, and a disguised Iago takes advantage of the ensuing confusion to cut Cassio's leg. Bystanders come to Cassio's assistance, and Iago also pretends to help. When Cassio starts to accuse Roderigo of attacking him, Iago covertly stabs and kills Roderigo to prevent the truth from coming out. He then lays the blame for the attack on Cassio at Bianca's door.

That night, Othello smothers Desdemona. Emilia enters the room to be told by Othello that Desdemona had been committing adultery. After a shocked Emilia calls for help, the outgoing governor of Cyprus arrives, along with Iago, Cassio, and others. When Othello adduces the handkerchief as proof that Desdemona was cheating, Emilia suddenly understands with horror that Iago has set up the whole situation. She exposes Iago, and he kills her.

Othello, now realizing Desdemona's innocence, wounds Iago, proclaiming that he wants him to experience pain for the rest of his life. Lodovico, a Venetian nobleman, captures Iago and Othello, but before Othello can be taken into custody, he commits suicide. Iago is led away to face torture, refusing to speak, and supplying no excuse or mitigation for the trail of havoc he has wrought.

### Iago's Deception

Iago has been described as one of Shakespeare's most evil villains, due mainly to the lack of any clear motivation for his malign behavior. Scholarly discussions of his character have therefore concentrated on the confusions surrounding motive: what drives him? Iago does not seem to be absorbed by the overwhelming self-interest shown by characters in other Shakespearean tragedies. His own passion appears to be for discord itself. He enjoys engendering conflict for its own sake.

The play closes with Iago vowing silence, and questions ultimately remain about the reason for his manipulations. He stands to gain little from them personally, other than the perverse pleasure derived from targeting and playing upon the insecurities of others. These insecurities need have no

basis whatever in reality. There is no evidence, for example, that Othello has been sleeping with Iago's wife. Iago also stirs and exploits racial tensions: Desdemona is white, Othello black, and Iago makes much of this. Throughout, Iago has no hesitation in lying where he sees an opportunity he can use, and his insinuations make these lies real and present, allowing him to "play" protagonists against each other like chess pieces.

He opportunistically uses the potential of disagreement and discord in a number of developing situations in order to prey upon his victims, identifying weak spots and fomenting conflict—seemingly for his own private enjoyment—wherever possible. The compulsion to spread doubt, then stand back and watch as mayhem is created,

Actor Edwin Booth appeared in numerous New York performances as Iago in Shakespeare's *Othello*, the Moor of Venice, in the late 1860s and early 1870s. Iago, who has been described as one of Shakespeare's most evil villains, has no hesitation in lying where he sees an opportunity to use it.

constitutes the core of his character. He relentlessly exploits the trust that others place in him, as “honest Iago,” to draw them into mutual hostility.

This drive to engineer catastrophes and destroy relationships has led to the suggestion that Iago is impelled by motiveless malice. He does appear to embody a spirit of disinterested disruption. The spectacle of harmony is anathema to him: Any opportunity for upsetting equilibrium, for pitting character against character, and ruining reputations, is gleefully seized. His cold maneuvering of those around him, and related inability to regard them as anything but raw material for the playing out of his malevolent schemes, has appalled generations of theatergoers. Many spectators and commentators regard him as a psychopath. Others associate him with the concept of evil. The vow of silence which he makes before he is led off at the end of the drama guarantees that the suggestion of impenetrable motivation will continue to be troubling, no matter what advances are made in the psychology of deception.

## Identity Theft

Identity theft has become a major crime in the United States, negatively affecting individuals and businesses alike. The Federal Trade Commission (FTC) estimates that around 9 million victims are affected annually. According to the FTC, identity theft is the unauthorized use of an individual’s personal identification information, such as a person’s name, Social Security number, and credit card, by someone else with the intent of using this information to commit fraud or other crimes. Identity theft can cause major disruptions to a person’s health, business, finances, and life. Identity theft requires a great deal of time, energy, and resources for the victims to recover from this crime.

### How Identity Theft Occurs

While there is no record of the first case of identity theft, the Oxford English Dictionary notes that the phrase was first coined in 1964. Identity theft can happen in different ways. Thieves can use an individual’s name to rent housing, set up phone lines, or obtain a credit card. Unless individuals diligently monitor their credit reports, they might not know about the theft until a debt collector contacts them, or they receive bills for charges they did not make.

Identity theft has become a lucrative business and causes financial burdens for its victims. Some victims might have to pay hundreds of dollars and spend days recovering their credit and life from the theft. As a result of identity theft, some victims can also be denied housing or job opportunities, education loans, and other services.

Identity thieves have several ways to obtain an individual’s information. The FTC lists the following methods: dumpster diving, skimming, changing a person’s address, old-fashioned stealing, pretexting, and phishing. With dumpster

diving, identity thieves search through a person's garbage for bills and other documents containing personal information. Thieves can also extract information from credit or debit card numbers by skimming, which is the use of a special storage device to process their victims' cards. Thieves can change a victim's address to redirect his or her billing statements to a different location by filing a change of address form. They also use old-fashioned methods of stealing, including misappropriating wallets, purses, bank and credit card statements, pre-approved credit offers, new checks, or tax information. They can also steal personal records or bribe those with access to them. Pretexting takes place when thieves make false pretenses to acquire personal information from financial agencies, telephone companies, and other institutions.

### Phishing

Thieves who "phish" for personal identity data pretend to be representatives of financial institutions or businesses, sending their victims spam or pop-up messages via the Internet in order to get victims to give them personal information. Of all the methods employed by identity thieves, phishing, also known as "Web spoofing" or "carding," is the newest and is likely to be the most prevalent in the future given the large amount of Internet use and the wide range of business activities conducted online. Looking at client-side defense against Web-based identity theft, Neil Chou and his colleagues from the Computer Science Department at Stanford University predict that phishing will continue to be a problem in the years to come.

Web spoofing is a major form of Internet crime, affecting as many as thousands of individuals on a daily basis. Typically, a bulk e-mail will instigate the fraud, urging unsuspecting consumers to click on a link that leads them to a spoofed site. The consumer will then be asked to log in, and once the username and password are entered, the identity thieves can access the consumer's account, usually to make a withdrawal or to cause other harm.

Web spoofing demands special attention because phishing can become more sophisticated in the future, while nonexpert Internet users might not be up to speed with the new tactics employed by spoofers. There has been an exponential increase in the number of phishing cases

over the years. Agents of the U.S. Secret Service's San Francisco-based Electronic Crimes Task Force received over 75,000 complaints in 2002, three times the amount filed the previous year. The estimated monetary loss was \$54 million in 2002, compared with \$17 million in 2001. Most of the \$37 million increase in loss between the two years was attributed to Web spoofing.

### Use of Personal Information

After the thieves have stolen personal information, they can use it in a multitude of ways. Some of the most common ways include credit card fraud, phone or utilities fraud, bank or finance fraud, and government document fraud. In a credit card fraud, the thieves may open new credit cards in the cardholder's name and then refuse to pay the bills, resulting in delinquent accounts listed in the cardholder's credit report. They may change the billing address on a credit card and incur charges on the cardholder's account. Because the original cardholder no longer receives bills, he or she will not notice the problem for a while.

Phone or utilities fraud takes place when an account is open in a victim's name or when charges take place in an existing account without the account holder's knowledge. Thieves can use the account holder's name to sign up for utility services, such as electricity, heating, cable TV, and gas. Bank or finance frauds involve thieves creating counterfeit checks with a victim's name and account number or opening a bank account in the victim's name and writing bad checks. They might also clone a victim's automated teller machine (ATM) card or debit card and withdraw money from the victim's accounts or get a loan in the victim's name. In government document fraud, thieves can use personal information to get a driver's license or official identification card issued in their victim's name but with their own picture, in order to receive government benefits or file a fraudulent tax return.

Identity thieves may use personal information, including a victim's Social Security number, to get a job, rent a house, obtain medical services, or give a victim's personal information to the police during an arrest. When they fail to show up for their court date, the victim is issued a warrant for arrest.

Once someone suspects that they are a victim of identity theft, they need to investigate their credit

report. If this investigation indicates an identify theft may have occurred, the victim should place a fraud alert on his or her credit record.

### **Consumer Sentinel Network**

The FTC has created the Consumer Sentinel Network (CSN), a secure online database with millions of consumer complaints available only to law enforcement. Besides storing complaints received by the FTC, CSN also keeps tracks of complaints filed with the Internet Crime Complaint Center, Better Business Bureaus, Canada's PhoneBusters, the U.S. Postal Inspection Service, the Identity Theft Assistance Center, and the National Fraud Information Center, among other agencies. Law enforcement agents throughout the world can access the database for investigations.

The CSN was set up in 1997 to collect fraud and identity theft complaints and since then has received more than 5.4 million complaints. In 2009 alone, the CSN received more than 1.3 million consumer complaints. Because the CSN also stores complaints transferred from other organizations, the total number of complaints is usually higher than that found in the initial annual reports.

### **President's Task Force**

In an effort to combat identity theft, former president George W. Bush established the President's Task Force on Identity Theft by Executive Order 13402 on May 10, 2006. The task force was authorized to spearhead the fight against identity theft and help ease the tremendous financial and emotional burdens of victims. The task force was to work with other governmental agencies to attempt to eradicate this crime.

The agency was charged with crafting a strategic plan in order to optimize the federal government's efforts to create awareness about, provide prevention against, instigate detection of, and carry out prosecution against identity thefts. The Task force is chaired by the U.S. attorney general and cochaired by the chairman of the FTC.

The task force focuses on various areas, including law enforcement, education, and government safeguards. In the area of law enforcement, the agency looks at the legal tools that can be used in preventing, investigating, and prosecuting identity theft crimes. The task force also examines ways to recover the proceeds of these crimes and to make

sure that the punishment of identity thieves is just and effective.

In the area of education, the task force reviews the educational efforts carried out by governmental agencies and the private sector to help individuals and businesses protect their personal information. In the area of government safeguards, the task force works in tandem with several federal agencies to determine how the government can augment regulations in order to maximize the security of personal data maintained by the government and private businesses.

The task force also engages in a wide range of activities to involve and inform the public in the fight against identity theft. The agency organizes meetings, talks with stakeholders, and solicits public comments on major issues pertaining to identity theft. Its strategic plan aims to strengthen efforts of federal, state, and local law enforcement officers; to inform individuals and businesses on how to deter, detect, and defend against identity theft; to aid law enforcement officers in capturing and prosecuting identity thieves; and to amplify the measures employed by federal agencies and the private sector to guard the personal data they hold.

The task force's Web site contains a "Guide for Assisting Identity Theft Victims," which the FTC developed to aid attorneys and victim service providers who work with pro bono clients.

### **Nongovernmental Assistance**

Several nongovernmental organizations have stepped in to help victims restore their identities. The Identity Theft Assistance Center (ITAC) is one of these organizations. Since 2004, the ITAC has helped tens of thousands of victims defend against identity theft. ITAC maintains it is not possible to eradicate identity theft, but it is possible to manage this form of fraud. A consumer advocate for victims of identity theft and a resource for the financial services industry, the ITAC is affiliated with the Financial Services Roundtable and supported by the financial services industry as a free service to its clients.

Members of ITAC provide the free victim assistance services to those who suspect their identity might have been stolen. ITAC minimizes the time to resolve a case by assigning a single point of contact to each suspected theft. A trained agent helps consumers recognize questionable transactions

and informs banks, credit companies, and other institutions about a victim's possible identity theft.

Despite the availability of services such as ITAC, the best defense for consumers is to have knowledge and awareness of identity theft. Consumers should also be aware of their rights in order to protect themselves and to take the proper actions toward eliminating fraudulent information from their credit reports.

goals related to one's group membership. Second, ideology is a set of beliefs that a society reinforces to its members to maximize control over the status quo with minimal conflict. Lying and deception play a role here when an individual and/or a society attempts to uphold these sets of beliefs. The first concept is related to how an individual deceives oneself, whereas the latter is related to how a society deceives its members.

Self-deception based on the first definition of ideology is exercised through cognitive control of individuals, both at the perceptual and conceptual levels of social judgments. Mass deception based on the second definition of ideology is exercised by symbols and cultural practices orienting people's understanding in such a way that they accept the current way of doing things. Psychologists advance knowledge about relationships between ideology and self-deception, while sociologists develop understanding about the interconnectedness of ideology and mass deception.

### Self-Deception: Ideology as a Perceptual Filter Toward the Social World

Self-deception based on one's ideological bias can be found from basic perceptual judgments to sophisticated higher order reasoning. Recent research in cognitive psychology sees ideological bias as a failure of information processing. This bias consists of stereotyped reasoning in which new information is distorted in order to make it conform to existing beliefs. People are far from the detached information processors that normative models of human judgments would prescribe. The term *bounded rationality* means that people are prone to systematic predictable cognitive biases. People are prone to systematic and predictable errors in making judgments and decisions because of ideological links between target judgments and the group to which the people feel they belong—in other words, revealing their "ideology-bounded rationality." People appear to be motivated by various factors to reach conclusions that color the self in a favorable position, leaving one immersed in self-deception.

Group affiliation can bias people to perceive the same stimulus differently and to draw inferences that protect and promote the interests of their in-group, as people derive their self-esteem in part from the meaningful groups to which

## Ideology

Ideology can be defined as two interrelated concept at an individual and a social level. First, it represents a set of beliefs that an individual holds to maintain one's identity and goals, especially

they belong. A classic demonstration of this self-deception based on social categorization can be found in Albert Hastorf and Hadley Cantril's "They saw a game" study. In this study, although students at Dartmouth and Princeton Universities viewed the same film of their respective school's football teams on November 23, 1951, it seemed from the results that they had watched two different games. While Dartmouth students tended to see Princeton's rule violations and Dartmouth's appropriate responses, Princeton students saw a continuing pattern of Dartmouth's rough play and occasional Princeton reprisals. The students from the two schools saw their side as the hero and the other side as the villain, regardless of reality.

As mentioned above, self-deception based on one's own desirable state of mind (ideology) is not only found in higher order reasoning, such as the fairness of play in a football game, but can also be found in perceptual judgments. For example, Emily Balcetis and David Dunning found that thirsty undergraduates see a water bottle in front of them located closer than it actually is. In relation to political ideology, Eugene Caruso and his colleagues have demonstrated that during the 2008 presidential campaign, Democrats perceived the face of Barack Obama to be lighter, whereas strong Republicans tended to see Obama's skin tone as darker than did liberals. Visual representations of the candidate fit coherently with the desire to see one's own group members positively.

This self-deception is not only the case for competitive contexts such as sports or politics. In a study by Jonathon Schuldt and Norbert Schwarz, people who identified themselves as caring more about proenvironmental values thought Oreo cookies made with organic flour and sugar had fewer calories than normal Oreo cookies. Obviously, however, the two products in actuality contain the same number of calories.

Contrary to the truism "seeing is believing," what actually happens is that "believing is seeing." People see what they want to see or see how they want to see. Self-deception based on ideology goes well beyond visual perception or conceptual judgments based on visual representation. Emerging works in motivated social cognition suggest that this perceptual distortion can happen in hearing, tasting, and even smelling. For example, organic and/or fair-trade chocolate tastes better

*A customer contemplates her selections in a chocolate shop in Zurich, March 2010. Research in motivated social cognition suggest that perceptual distortion can occur in the senses. For example, supporters of organic and/or fair-trade chocolate report that their ideologically supported chocolate tastes better.*

to those who are supporters of fair-trade policies. Even in the face of simple perceptual facts, people often find themselves falling prey to just plain wrong ideas, exhibiting self-deception because of ideology.

Self-deception as a consequence of ideology produces a variety of social psychological by-products as well. Ideological bias can lead people to pluralistic ignorance—an erroneous perception of the relationship between one's own opinions and those of the majority. Misreading public opinion consistent with one's own opinion, an individual is actually in the majority but falsely believes he or she is in the minority. This self-deception of opinion climate because of one's ideology can also happen the other way around, producing false consensus. False consensus is the inaccurate perception that other's beliefs are similar to one's own belief, when they are not similar in reality.

Taking a step forward, false consensus also includes seeing one's judgments and behavioral

decisions as more socially desirable and commonly accepted, while considering alternatives as inadequate and deviant. Projecting one's own ideology (beliefs and values) in seeing other's social judgments leads people to hold these self-deceptions about generalized others in a society. The cases of pluralistic ignorance and false consensus are well witnessed in American history. For example, a series of studies in the 1970s—when the racial conflict was at its peak in the United States—reported that while college students overestimated the support for affirmative action on campus, people depicted most Caucasians as being against racial equality in their communities.

### **Mass Deception: Ideology as Construction in the Service of Power**

Mass deception based on a society's need to maintain the pre-existing order goes back to Greek mythology. Myths provide answers and explanations for everyday questions. However, myths are not necessarily true but actually are more often fictional stories created in order to maintain order in society. Among Joseph Campbell's four functions of myth—the mystical (awe-inspiring), cosmological (describing the nature of the universe), sociological (supporting or validating certain social orders), and pedagogical (providing models for living) functions—the relevance of myth here pertains to the latter two, not the former two.

In the modern era myth gives way to ideology. Karl Marx and Friedrich Engels employ the generic term *ideology* in order to explain how cultures are structured in ways that enable a group in a society to maintain control. Ideology does not necessarily refer only to a process in which groups deliberately plan to oppress people or alter their understanding about how their interpretations of the social world should be. Ideology can be more broadly defined as any attempt to naturalize social practices that have a deep historical origin.

Dominant social classes or institutions in society use symbol systems and social entities such as values and attitudes in such a way as to legitimize the current state, order, or power structures and make them seem “natural.” For example, an argument like “men are better at math and science, whereas women are better at languages” can be a strategic effort to naturalize alleged differences between women and men, naturalizing

the superiority of one gender. The historical roots of social expectations about men and women are deleted here, and what is left is an historical stereotype of gender roles. This is also the case for racism. It endorses social practices reflecting the belief that human beings can be categorized into distinct biological groups called race, which assign a certain group of people with specific “natural” attributes.

In contemporary society, ideology permeates the general public as mass deception through various channels. One of those outlets in which individuals can easily find ideology is popular culture, such as soap operas, movies, and popular music. For example, the movie *Independence Day*, which had a huge box-office success, depicts a war against the aliens from outer space with naturalizing racial differences through action-packed spectacle and computer graphics. In the movie, the three main characters—the president of United States, a scientist, and a soldier—struggle against the attacking aliens. Here, the president who takes charge in the war against the aliens is played by a white Caucasian actor; the scientist who uses his brain to attack the aliens is depicted as Jewish; and the soldier who is shown in most of the physical engagements (hand-to-hand fighting) against the aliens is played by an African American actor. The roles played by these three characters/actors reiterate cultural stereotypes about race and ethnicity, strengthening this ideology to its audience members.

In addition to media content, various social institutions play a significant role in molding cognitive and affective interpretations of the social world consistent with ideologies. Louis Althusser dubbed these social institutions, such as schools, churches, and even families, the “ideological state apparatus.” According to Antonio Gramsci, these institutions combined with cultural practices, such as literature and media entertainment, to provide hegemony (legitimacy) to certain ideas (ideologies).

Historically, ideology has been a focal point of criticism. The first critic of ideology was Napoleon Bonaparte. Specifically, he criticized the “ideologues,” meaning a group of theorists at the time that provided arguments based on the human need for self-serving illusion as opposed to the need for political reality. At first, the criticism was mainly about a detachment of theory from

reality (the discrepancy between an idea and how the social world works). Later, Marx and Engels employed the term *ideology* as an agent of “false consciousness.”

What is interesting about ideology as mass deception is the fact that an ideology can be called out as an ideology only when it is discovered as unnatural. This notion can be exemplified by the popular anecdote appearing in the movie *The Matrix*. People in *The Matrix* (signifying a society with mass deception based on ideology) do not realize that they live in the Matrix. If one takes the blue pill and stays in the state of “ignorance is bliss,” one cannot realize that one is succumbing to ideology. It is only when one takes the red pill that one can see the bitter reality.

Critical theorists have long tried to identify ideologies. For example, Roland Barthes analyzed the operation of the mass deception process based on ideology (social order) in everyday life with an example of a photograph on the magazine cover of *Paris Match*. The photo displays a young soldier in a French colonial country. The soldier, wearing the military uniform of France, is shown giving a salute to the French flag. On the surface, it is a young soldier from a French colonial country in his uniform. But in closer analysis, what the photo means, according to Barthes, is the ideology that France is a great nation; France gives an equal opportunity to its colonial people with no racial discrimination. The reason why it is difficult to call this out as ideology is because people often overlook its meaning and see it as a mere magazine photo.

### Conclusion

Ideology plays a significant role in both self-deception and mass deception. Although the very definitions and mechanisms by which ideology works in deception vary in terms of the level of analysis, both psychological and sociological approaches to the role of ideology in self- and mass deception reveal a crucial implication: Deception based on ideology can change human history. The reason why people should pay attention to and reflect on their own ideology with constant vigilance lies here.

## Impression

Like a footprint pressed into the sand, where there is an impression, something remains in presence by virtue of its mark, as if it were the very essence of the thing. Thus, there are good impressions, false impressions—frightening, awkward, and ridiculous impressions—all sorts of impressions that persist as traces of the people, locations, or events they represent. Nothing can present all facets and perspectives of itself at once; even a dot on a page looks completely different under a microscope. Thus, we have only limited knowledge of things, only impressions to go by. As Ginsberg famously said, “America, this is the impression I get from looking in the television set.”

With respect to persons, this is also true. Others cannot know everything about who a person is; they cannot even know this of themselves. Nevertheless, they often take up momentary impressions, as if this solves the puzzle of the other person.

Common expressions such as “first impressions last,” and “be sure to make a good impression” exist because where first impressions succeed, they persist, and where they fail, it is hard to recover from them. For example, Mr. Darcy of *Pride and Prejudice*, originally titled *First Impressions*, initially seemed “the proudest, most disagreeable man in the world.”

Self-consciousness arises when individuals realize that others will and do form impressions of

them. In the work of Jean-Paul Sartre, being gathered as an impression in the eyes of another is referred to as subjection to “the look,” and an intention to perform an impression for others, a cliché of oneself, is referred to as “bad faith.” It is a tendency well illustrated in the movie *Annie Hall*, when subtitles reveal the impression anxieties of Alvy and Annie as they speak to each other.

### Success and Impression

There is much evidence that people believe they succeed if they impress. In romance, for example, impressions have been created in newspaper ads, video date services, telephone matchmaking services, speed-dating groups, and the more recent Web-based matchmakers. For the sake of impression, a person will wash and wax a car before selling it, detail a house before putting it on the market, and spend a day at the beautician before a date. Cosmetic surgery, designer homes, beauty creams, name brands, high fashion, jewelry, luxury automobiles, chrome rims, cigars, wines, and other forms of ornamentation evidence the concern with impression. Women augment their breasts and men graft their hair because they believe that success, however they conceive it, is more likely if they can create a winning impression. Some acts of war are done to create impressions awesome enough to paralyze an enemy, such as America’s “shock and awe” campaign in Iraq.

All such impression mongering is shaped by cultural context. The *izixolwanas* necklace, worn by women of the Ndebele tribe, provides an example of culturally specific ornamentation to create a winning impression, as do the bound feet of traditional Chinese women, or the corseted women of the West.

### False Impressions

The expression “put your best foot forward” is grounded in important folk wisdom with respect to impression: it takes for granted the notion that one can positively shape one’s image without resorting to falsehood. All the same, it is difficult to decide whether false impressions are given by a plumber in a tuxedo or Cinderella at the ball—they are grey area performances best governed by the expression “fake it till you make it.” However, not all cases are grey. The guitarist carrying

a guitar gives an accurate impression, and the boy with a false ID at the liquor store gives a false impression.

The issue of falsified impressions is thoroughly discussed as early as Plato, in writings such as *Phaedrus*, *Gorgias*, and *The Sophist*. In the *Gorgias* (462–66), for example, Socrates claims that the wise person will commit to four things: nutrition, fitness, divine law, and justice. Others can be fooled, however, by false impressions of these things. The impression of nutrition can be falsely given by or misrecognized as haute cuisine, and the impression of fitness can be falsely given by or misrecognized as self-adornment. The impression of divine law can be falsely given by or misrecognized as authoritarian pronouncement, and one can be steered from reasoning with justice by its deficient cousin, persuasion. Socrates’s words are relevant to political campaigning, advertising, public relations, and propaganda; yet they are also on display in individual lives. All the same, Socrates and Plato take a harder line on impression making than that taken either before or after them. Even drama was castigated as the creator of false impressions by Plato, and he would equally oppose any games that involved deception, unless they were part of training for warfare.

Creating false impressions by misrepresentation or lying is not uncommon. Archbishop Fulton J. Sheen, who was the author of more than 20 religious books, as well as a famous television and radio celebrity, and who is now well on his way through the process of Catholic sainthood, began falsely adding a second doctoral degree (his was a Ph.D., but he illicitly added the theological doctorates, alternating between the S.T.D. and the D.D.) to his list of titles, though he did not have either. One may not only create a false impression for oneself but even others by lying, as Iago does for Desdemona in the Shakespearean play *Othello*.

A false impression may have a high level of functionality, so long as it remains undetected. Bigamists, for example, are able to raise two families thanks to false impressions. It is not easy for falsifiers to create such illusions, but they may be aided by others who develop strategic blindness with respect to the façade in order to preserve the functional unreality. This is a form of conspiring

to preserve an illusion, or collusion. Deceptive impressions are always on the verge of collapse, however, and when they do, the real world created by their falsehoods may fall as well. Some economists believe that this is currently the case with respect to the American economy.

A poorly contrived false impression does the performer more harm than good because it ads impostor or sham to whatever is the list of vices already noticed by others. In Dickens, the transparent false impression reaches its apotheosis in *Copperfield's* Uriah Heep, who rubs his hands in ambitious greed while pronouncing that he is "so 'umble."

### Sham and the Falsified Impression

Sham is said to exist when people give false impressions of who or what they are. Thus, the unexpected camera at Ron Brown's funeral gave President Clinton's grief there the quality of sham by catching him swing from lightheartedness to tearfulness when he spotted it.

Sham is also used to create false impressions of feelings or thoughts. One can sham warmth, concern, joy, judiciousness, impartiality, or indignity—one can perform any emotion, gentility, or consideration as present when it is not present. All the same, the sales clerk who says "May I help you?" may very well want to help. She will only move toward a sham performance of her role when a substantial gap arises between her impulse to spontaneously self-express what she feels and her need to falsify an appearance. If, for example, she thinks the customers in her store are all women who refuse to face the fact that they have grown old, but she works on commission, she may be shamming when she says that one of them looks "10 years younger in that dress."

Sham is also used to move things along while preserving social grace. Thus, one can receive or give sham congratulations, thanks, compliments, or concern. Such sham moments allow social agents to skate over the thin ice of false intimacy, without having to address every corruption they encounter. Where interest is shammed (e.g., "What a delightful story!"), its recipient is expected to say, "Thank you, but I've kept you far too long." Where welcome is shammed (e.g., "Won't you sit down?"), the recipient is expected to construct a reason to keep moving. Where

invitation is shammed (e.g., "You're certainly welcome to come too!") the recipient is expected to be busy on the occasion of the event.

Generally, it is considered tactless to unmask a sham performance, and there are cultural sanctions against doing so. Calling out sham (which Erving Goffman was known to do) therefore requires power, naïveté, or anger so great that caution is thrown to the wind.

Sham performances are deceptive and false, but they cannot be reduced to lies in any facile manner, for falsehoods of this kind are governed by a variant of the mutual understanding that play is occurring between the agents involved. Much like flirting, in which participants give a false impression of their availability or interest while signaling in more nuanced ways that the faux seduction is a game, sham participants also signal to each other that they are being theatrical, as if to say "Let's fake our way through this awkward moment rather than address the explosive truth." Effectively, then, sham is a social norm, one customary manner of facilitating social process. This is what Queen Elizabeth did when she artfully gave the impression of being oblivious to Rene Levesque's chain smoking as they stood face-to-face (she turned her head when he inhaled). Levesque, who could not be without a cigarette, also played his part in shamming propriety by hiding the cigarette when it was not in his mouth and covering it with his hand when it was. Their tactful sham strained the very limits of impression management; nevertheless, it prevented any discussion of the status relations that might exist between the queen of the empire and the leader of the French separatists in the Canadian province of Quebec.

### Black Sham

Living sham as if it is real can create havoc for both persons and communities. Unhappy couples may sham an impression of happiness, only to extend the time that they are miserable together. Parents may sham feelings toward their children, only to give their children a deep sense of life's hypocrisy. Such acts were identified as "black shams" by cultural anthropologist Jules Henry.

The term *black sham* is somewhat dated, but the idea it characterizes is quite alive. "Don't ask, don't tell," for example, repealed in 2010,

advocated shamming sexual reality in the military, thereby exacting an overwhelming burden on the identity of gay soldiers at both a psychological and social level. To be instructed to deceive by one's government as a condition for employment is dark in precisely the way Henry used the term. Yet, the institutionally mandated gay closet is but an example of how persons may suppress imminent selfhood to create a normative impression, and this can wreak havoc on identity. A person whose true self has been long hidden behind strategic impressions may say, "I am a sham."

Those who build their lives with sham are rewarded with sham lives. The pretend person lives in a pretend house, engages in pretend pleasures, has a pretend spouse, and socializes in pretend ways with pretend friends; in the midst of all this, there is no place for the real person already lost in the house of mirrors. This is the theme of Kurt Vonnegut's *Mother Night* and the meaning of his aphorism "We are what we pretend to be, so we must be careful about what we pretend to be." To lose oneself in the middle of giving the impression one is something else—this is the poison of black sham.

## Inca Empire

Deception played a key role in the Spanish conquest of the Inca Empire. The conquistador Francisco Pizarro's dishonesty was an essential element

in the capture and execution of Atahualpa, the Inca emperor, in 1532. After the conquest, the mistrust between the Spanish and Inca people grew and deeply influenced their interactions.

### Pizarro's Deception

The Spanish conquest of the Inca Empire was led by Pizarro, who arrived in Peru in 1532 with 169 Spanish soldiers. During this time, the Inca Empire was in the midst of a war of succession. A civil war had broken out between two brothers, Atahualpa and Huáscar, which greatly weakened the empire by the time the Spanish conquest began. Atahualpa won the civil war and took Huáscar as a prisoner. Despite the empire's weakened state, Pizarro's forces were small, so careful planning on his part was necessary in order for his conquest to be successful.

Pizarro strategically deceived Atahualpa, the ruler, on more than one occasion in order to gain the upper hand. Upon hearing of Pizarro's arrival, Atahualpa was unsure as to whether he should consider the Spanish as thieves and murderers or as gods. Atahualpa avoided being deceived into believing Pizarro was a god when he heard scout reports of the violence that Pizarro's forces inflicted upon the local people. Atahualpa decided that he should trap and murder Pizarro.

At this point, Pizarro organized a meeting with Atahualpa. When they met, Atahualpa explained the reports he heard, which led to Pizarro's first significant act of deception: Pizarro denied the reports of his military actions. Because Atahualpa had no substantiated information, he decided to meet with Pizarro again in Cajamarca rather than execute his original plan to murder Pizarro. Whether or not Atahualpa trusted Pizarro at this point is unclear, but Pizarro's deception and denial of his actions was one of the main factors that kept him alive after their meeting.

The following day, Atahualpa entered Cajamarca with between 3,000 and 7,000 men, and approached the Spaniards with unarmed forces as a sign of goodwill. In contrast, Pizarro strategically placed his armed forces around the square where the meeting would take place. During their conversation, both sides grew impatient as neither side fully understood the other's requests. Eventually, Pizarro signaled his men to attack, which began the Battle of Cajamarca. Having

never seen horses or gunfire before, Atahualpa's men offered virtually no resistance against the Spanish cavalry charges, and Atahualpa was successfully captured. Pizarro's forces suffered very few casualties.

Once captured, Atahualpa was held in what became known as the ransom room in Cajamarca. Atahualpa offered to fill the room with gold and to give twice that amount in silver in exchange for his freedom. This is when Pizarro's next significant act of deception occurred. Pizarro accepted Atahualpa's offering, and received the payment in gold and silver, but did not release him. Some sources argue that Atahualpa's payments were not intended as a ransom payment but as an attempt to avoid being killed. Regardless, Pizarro deceived Atahualpa by falsely agreeing to fulfill his requests in exchange for the payments. Atahualpa was executed days later.

### Mistrust After the Conquest

After the conquest, mistrust between the Spanish and Inca people increased, and conflicts regarding record keeping arose. The Incas had developed their own system of maintaining records, known as *quipus*. These were simply bundles of cords, with knots made along the cords to record different things. Each community in the empire would appoint people as the record keepers, known as *quipucamayocs*, who would keep track of tribute payments, livestock, food, and any other item or activity that needed recording. The Incas placed great trust in the quipus, and quipucamayocs' testimonies and records were used in court trials.

This confidence deteriorated after the conquest because the Spanish did not understand how to read the quipus, and so they had to take the Inca record keepers' word about what the quipus said. At first, the Spanish were willing to listen to the quipucamayocs; however, the Spanish had their own bookkeeping methods, and these records began to conflict with those of the Incas. The Spanish became less willing to trust in the quipucamayocs and their records, and instances of deception arose in which the quipus played key roles.

Spanish chroniclers began to describe situations in which the local people demanded payments from Spanish governors for food they provided. The local people, however, were aware that

these demands for payments were usually met with compromises and that they would receive less than what they requested. As a result, Spanish chroniclers described how local people began to record larger payments in their quipus than what they were actually owed, so that when a compromise was reached with the governor, they would receive full payment.

There were also doubts regarding the accuracy of the Spanish notarial records. Even the Spanish monarch, Philip II, became aware of the lack of truthfulness in notarial records, and Spanish reports described how unqualified people were often appointed as notaries. Because of these conflicting reports, it is difficult to know for sure which side was initially deceitful in its accounting methods. However, regardless of who was to blame initially, the conflicts created by the quipus became important enough that in 1583, the Third Council of Lima ordered that all quipus be destroyed.

After the council's order, the quipus were used for a new, and often deceptive, purpose. Priests encouraged the local people to record their sins using quipus and to bring these records to confession. These quipus used cords and knots of different colors to represent different types of sins. This practice was encouraged at first, but the clergy soon realized that the local people were creating quipus and passing them along from one confessant to another, making it easier to lie about sins during confession. Once the priests realized this was happening, they devised methods of detecting this form of deception. They developed different interrogation techniques, such as asking the confessants more detailed questions about their sins in order to make sure that they were not being deceitful.

### Conclusion

Deception played an important role in the fall of the Inca Empire. The Spanish conquest of the Inca Empire, led by Francisco Pizarro, involved the strategic use of deception that ultimately led to the emperor Atahualpa's capture and execution. After the conquest, the Spanish had to contend with Inca accounting methods. Unable to understand these techniques, the Spanish began to distrust the records kept by the local people. However, Spanish chroniclers report that

the Spanish notarial records were also untrustworthy. Deceit in record keeping from both the Spanish and the Inca people was a source of conflict that led to the elimination of quipus from official record keeping.

## Infidelity

What constitutes an act of infidelity depends upon the exclusivity expectations within a relationship. Regardless of whether this act of cheating, adultery, or having an affair with someone other than one's partner refers to physical encounters, such as sexual intercourse or kissing, or a deep emotional attachment, deception is an integral part of infidelity. In order to successfully maintain an illicit affair, an individual must be able to keep the knowledge of his or her cheating away from the spouse or partner. The extent to which they are successful in doing so often decides the course and time span of the infidelity. While many people believe the worst part of infidelity is the physical or emotional cheating, individuals who have been cheated on often say that the hardest part of the situation to overcome is the lying and deception their partners' engage

in to hide the affair. The lies that accompany infidelity not only can shatter the trust between partners in a relationship, they can also shatter the victim's belief in his or her own ability to see people for who they really are and to know what is the "truth."

### The Lies Cheaters Tell

One of the things that makes recovering from lies told to hide an infidelity so challenging is that, when cheating occurs, self-protective lies are often told under the guise of protecting the relationship. Often the unfaithful spouse claims to have lied to their partner in order to protect him or her from being hurt. For example, most victims of cheating partners are told, "I didn't tell you because I didn't want to ruin our marriage and family." While this may not be completely untrue, much if not most of the motivation for lying about cheating stems from a desire to protect the self from censure for bad behavior and the accompanying punishment. If spouses truly desire to protect their marriage and family, they are unlikely to be engaged in an ongoing extradyadic affair. Even when the perpetrator truly believes that he or she is lying in order to protect the partner or relationship, at least part of their motivation is to downplay their own culpability and the seriousness of their actions, as if the partner not finding out about the affair somehow makes the affair itself less problematic. Most often though, the perpetrator is focused on trying to avoid as much conflict as possible while at the same time trying to maintain a self-image as a good person.

Second, lies told in romantic relationship situations are rarely one-offs. One of the problems with lying in these types of relationships is that once the individual starts lying, he or she has to keep up the pretense. The lies cheaters tell are complex and occur over a longer period of time than many other deception-related transgressions. In an ongoing affair, steps must be taken to hide the contact between the cheater and the extradyadic partner. E-mails, texts, phone calls, monetary expenditures, mysterious disappearances, and unexpected sightings by third parties must all be explained to the unsuspecting (or suspecting) relationship partner. These lies must build upon one another to form a cohesive story that will, the perpetrator hopes, protect the affair

from being discovered. The problem is that these lies frequently come back to haunt the teller, who must then remember the lie, repeat the lie, and likely tell even more lies to maintain the original deception. This is particularly true with complex lies in which the lies are being told in order to continue with a deceitful behavior, such as an ongoing infidelity.

Third, the lies people tell and deceptions people enact in courtship and relationship infidelity situations vary from those told to strangers and acquaintances in at least two other vital ways. While most research on lying treats this type of deception as an individual act committed by one person upon an unknowing party, there are some relational circumstances in which the receiver or target of the lie is directly involved in its perpetration.

The first type of jointly constructed lie is known as *connivance*. In these cases, for whatever reason, the target of the lie chooses to pretend that he or she does not know that deception is being practiced by his or her partner, when in fact he or she is acutely aware of the deception. This form of deception may arise for a number of reasons, the most obvious of which is that the victim cannot or will not leave the cheater and does not expect the cheater to change. A partner or spouse in this situation may choose to “ignore” the infidelity and the lies that accompany it, pretending to believe the stories being told by the cheater in order to avoid having to deal with the root causes of the infidelity or simply to avoid conflict and remain in the relationship. Connivance can also arise if a partner believes he or she is somehow to blame for the partner’s cheating behavior or that the cheating is somehow filling a gap in the relationship.

The second jointly constructed lie is known as *collusion*. In collusion, the teller and receiver of the lie agree in advance to collaborate in deception. In terms of infidelity, this type of collusion is thought to have occurred when one partner tells the other up front that if he or she has an affair, “do not tell me about it.” In essence this means, “If you have an affair I want you to lie to me about it.” This type of joint deception is often used when the punishment for telling the truth may well equal the punishment for lying about the action. In theory, collusion allows the victim

to remain ignorant not only of the infidelity but also of any problematic issues in the relationship. On the other hand, it essentially gives the cheater a license to cheat—as long as he or she does not get caught.

### Unmasking Infidelity

Contrary to the beliefs held by most cheaters entering into an affair, many infidelities are discovered. Complicated webs of lies are difficult to maintain over time, so often the finely tuned scenario implodes, leaving a partner betrayed. The method of discovery that leads to the least damage is one in which the cheating partner confesses to the affair without being caught or even accused. The shorter the amount of time that elapses between the cheating and the confessing, the better it is for the cheater and his or her spouse. This rarely happens, however. Most infidelities are discovered when the cheater confesses after being accused by his or her partner, when a third party observes the cheaters and reports this activity to the spouse/partner, or when the cheater is “caught in the act.” The latter modes of discovery, not surprisingly, result in the highest levels of damage to the relationship and drastically increase the difficulty of obtaining forgiveness and reconciliation.

When an infidelity is not uncovered, however, it is usually not because of a lack of clues, but because of the spouse engaging in truth bias. People generally believe that they are much better and more successful liars than their partners. When they aren’t sure if their partner is lying or not, they consistently err on the side of extending him or her the benefit of the doubt. This suggests that people are in essence good at recognizing the truth and poor at recognizing (or accepting) their partner’s attempts at deception.

When suspicious, however, the betrayed partner will often engage in deceptive acts in order to uncover their partner’s infidelity. Secretly hiring private investigators; surreptitiously checking the cheating partner’s e-mail, cell phone, and global positioning system (GPS); and following the partner in the hope of catching him or her “red-handed” are common tactics used by suspicious spouses who are motivated to uncover the truth about their partner’s faithfulness. The betrayed partner will often justify these covert actions as being less serious than the actions that

precipitated them, suggesting that by lying in the first place the cheating partner has forfeited his or her right to privacy. While many people would agree with this perspective, the reality is that many “snooping spouses” end up feeling bad about their undercover activities regardless of what information they are able to unearth.

### The Aftermath of Infidelity Discovery

Once an affair, sexual or emotional, has been discovered decisions must be made by the couple as to how to proceed. Infidelity was the impetus for approximately 50 percent of couples

*Contrary to the beliefs held by most cheaters who engage in an affair, many infidelities are discovered, such as when they are caught in the act. This mode of discovery results in one of the highest levels of damage to the relationship and drastically increases the difficulty of obtaining forgiveness and reconciliation.*

entering relationship counseling. Hurt feelings, negotiating the disclosure of further details, and issues with trust, communication, and intimacy must all be addressed if the couple has chosen to try and repair their relationship. One of the stumbling blocks many couples experience during this time is the systematic variation in the ways that perpetrators and victims view transgressions. Research has shown that victims tend to view transgressions of all types significantly more negatively than do the perpetrators of these transgressions.

Perpetrators often try to downplay the seriousness of their actions, an approach which victims of infidelity find particularly offensive. For example, while the common perpetrator refrain “it meant nothing to me” is intended to reassure the victim that the impact of the infidelity on the relationship was minimal, it often has the opposite effect of hurting the victim even more. Perpetrators will also try to isolate the incident, suggesting it was a one-time (or at least one-partner) aberration, or blame the affair on their spouse (“I wouldn’t have done it if you were nicer to me”) or the extradyadic (“She seduced me”).

Victims, on the other hand, are more likely to broaden the incident (“You’ve lied to me about other things in the past”), doubt the perpetrators’ truthfulness in claiming there have been and will be no other affairs, and be highly offended by the suggestion that they are somehow responsible for their partners’ unfaithfulness. Honesty and “the truth,” therefore, are very much in the eyes of the beholder, and perpetrators of infidelity can and should expect that their partner will be highly suspicious of any claims they make to positive or improving behaviors. Full and honest disclosure of pertinent information and future transparency of actions, thoughts, and issues are necessary components of recovery from the trauma of deception and infidelity.

## Information Manipulation Theory 1

Information manipulation theory (IMT) is a theory of deception authored by Steven McCornack that describes the nature of deceptive message design and the inferential process through which deceivers dupe listeners. IMT suggests that when people mislead others, they play with or "manipulate" information along multiple dimensions in myriad ways. These information dimensions align with the conversational maxims proposed by philosopher Paul Grice as undergirding conversational sense-making and implicature generation.

IMT has its roots in McCornack's doctoral dissertation. For his data collection, McCornack had a sample of college students report situations in which they had lied to romantic partners. McCornack then edited these situations (replacing the original names with gender neutral names; changing the tense from past to present) and administered them to a different sample—asking participants to write what they actually would say if they were in that situation. Based on previous research involving recollected messages, McCornack presumed that his data would be easily codable as "truths," "lies," "concealments," and other descriptions. However, the message variation in his data defied extant taxonomies. This poorness of fit caused McCornack to rethink how deceptive messages can best be described. He concluded that deceptive messages should be

conceptualized multidimensionally rather than as categorical "types."

### Dimensions of Information Manipulation

McCornack argued that deceptive messages involve two broad dimensions of information manipulation: the amount of relevant information that is (or is not) disclosed, and whether the information that is disclosed is truthful or distorted. This two-dimensional model of deceptive message design (that is, Amount  $\times$  Type) was presented as a conference paper at the Speech Communication Association (SCA) conference in 1988, "The Logic of Lying: A Rational Approach to the Production of Deceptive Messages."

Subsequently, McCornack revised his two-dimensional model to include four dimensions of information manipulation, based on Grice's theory of conversational implicature. The revised model was presented at an SCA conference in 1990 ("Lying as a Pragmatic Phenomenon: A Theoretical Framework for Addressing Deceptive Message Design") and subsequently was published as "Information Manipulation Theory" (or "IMT") in *Communication Monographs* in 1992.

### Violations of Conversational Maxims

IMT argues that during everyday conversations, people orient to four "Gricean" maxims: quantity (the amount of relevant information that is shared), quality (the veracity of shared information), manner (the way in which disclosed information is expressed), and relation (the relevance of disclosed information). People expect that these maxims will be adhered to as a part of the broader norm governing rational and coherent human discourse, which Paul Grice labeled the cooperative principle (CP): "Make your conversational contribution such as is required, at the stage at which it occurs, by the accepted purpose or direction of the talk exchange in which you are engaged."

In cases of deception, however, people exploit this expectation of cooperativeness. As McCornack describes, "It is the principal claim of information manipulation theory that messages that are commonly thought of as deceptive derive from covert violations of the conversational maxims. Because the speaker purposefully violates one (or more) of the maxims, s/he deviates from what can

be considered rational and cooperative behavior (i.e., behavior that adheres to the CP). Because the violation is not made apparent to the listener, the listener is misled by her/his assumption that the speaker is adhering to the CP and its maxims.”

The message-design implication of IMT is that people have at their disposal an indefinite number of ways they can play with or “manipulate” information in order to deceive others. As McCornack described in the conclusion, “Given that conversational interactants possess expectations regarding information quantity, quality, manner, and relevance, it is possible for speakers to violate any or all of these expectations in attempting to deceive listeners.”

Several additional implications for research and scholars in the field of deception derive from IMT. First, and arguably most important, natural discourse does not take the form of dichotomous “truths” and “lies.” Instead, most messages fall somewhere “in between” these two (comparatively rare) types, and most deceptive messages involve both truthful and false information elements. Second, people commonly deceive others through the presentation of messages composed entirely of truthful information—but that leave out key elements of relevant information (that is, quantity violations). Third, scholars of deception should abandon categorical coding schemes that force fit observed messages into “types” or that experimentally manipulate dichotomous characterizations of messages (for example, studies that pit “bald-faced truths” versus “bald-faced lies”). Instead, scholars should focus their analytical attention upon naturally occurring messages, then code these messages in terms of the multiple dimensions of information that flow within them.

### Critiques of Information Manipulation Theory

Immediately following the publication of “Information Manipulation Theory,” two sets of scholars offered substantial critiques. Scott Jacobs and his colleagues argued that IMT misrepresented Grice, in that deception isn’t caused by violations of Grice’s maxims per se but instead by the deceptive implicatures that such violations trigger. Dave Buller and Judee Burgoon suggested that rather than the four information dimensions conceptualized by Grice and embraced by IMT,

in fact five information dimensions exist along which deceivers manipulate information—the additional dimension being “immediacy.”

In 1997, McCornack offered his own critique of IMT, arguing that “IMT is not actually a theory at all: it provides no testable propositions or falsifiable hypotheses, hence, fails to meet the established criteria for viable social scientific theory.” In 2012, on the 20th anniversary of the publication of the original IMT, McCornack sought to rectify this shortcoming by presenting a propositional theory of deceptive discourse production rooted in the arguments of the original IMT, dubbed “IMT2.”

## Information Manipulation Theory 2

Information manipulation theory 2 (or IMT2) is a propositional theory of deceptive discourse production, originally presented at the National Communication Association conference in November 2012. Rooted in extant research and theory on cognitive science, speech production, and artificial intelligence models of problem solving, IMT2 explicates the production architecture underlying deceptive discourse and then presents a series of 15 testable propositions.

IMT2 is an elaboration of arguments presented by Steven McCornack in two previous works: his journal article "Information Manipulation Theory" and a chapter on deceptive message production written for *Message Production: Advances in Communication Theory*, edited by John O. Greene. In his article on IMT, McCornack suggested that when deceiving others, people play with or "manipulate" information along multiple dimensions in myriad ways that align with the conversational maxims proposed by philosopher Paul Grice. However, because such manipulations are covert rather than overt, listeners are misled.

In his book chapter, McCornack proposed that the production of deceptive discourse can best be characterized as a process of opportunistic problem-solving in which individuals reason through difficult situations, and opt to manipulate information

as the most efficient solution for resolving gaps between current problematic states and desired end states. Similar to these earlier offerings, IMT2 conceptually frames deception as involving the covert manipulation of information along multiple dimensions, and as a contextual problem-solving activity driven by the desire for quick, efficient, and viable communicative solutions.

The cognitive discourse-production architecture posited by IMT2 derives from six sources: the theorizing of linguist George Zipf; the blackboard model of problem-solving suggested by H. Penny Nii; principles of design theory forwarded by Vinod Goel and Peter Pirolli; Bernard Baars's global workspace theory; Theo Herrmann's Mannheim model of speech production; and the work of Gary Dell, Franklin Chang, and Zenzi Griffin on lexical encoding patterns.

From these sources, six foundational premises about the nature of the mind, discourse production in general, and deception in particular undergird IMT2: (1) given its frequency, deceptive discourse must present cognitive efficiency advantages over truth-telling; (2) deception derives from opportunistic problem-solving; (3) message design decisions that guide communicative output are driven largely by memory retrieval, not top-down reasoning; (4) deceptive discourse—like all discourse—is not produced as discrete, unitary "messages" in a sequential, linear fashion, but instead results from a series of "microbursts" of mental activity, consisting of cyclical processing, as consciousness interacts with unconscious, modular subsystems including memory, motivations, and speech production; (5) discourse production begins with the construction of a cognitive representation of the situation, which activates relevant information in memory; and (6) the production of spoken discourse occurs incrementally, with the "front end" of utterances being spoken as the "tail ends" are still being designed.

Synthesizing these disparate influences into a coherent whole, IMT2 suggests a multistage architecture of deceptive discourse production. First, a cognitive representation of the "current state" is constructed that activates associated information within memory, in a spreading-activation fashion, feeding a "propositional base" of information potentially relevant for disclosure. Second, this situational representation is compared

against a desired end state, based upon conscious and unconscious goals, motives, and intentions. Third, an “action course” through the “problem space” is plotted, based largely on efficiency of solution. Fourth, truthful information within the propositional base that efficiently resolves current-state/end-state discrepancies is fed to speech production in the form of lemmas (nonphonological cognitive representations of words), that are then translated into phonological form and output as spoken discourse. Fifth, current-state/end-state discrepancies that cannot be resolved efficiently through disclosure of truthful information will be resolved by suppressing the information, veiling it through ambiguous word forms, or presenting false information. Sixth, in instances of false-information disclosure, information will be fed to speech production that is most easily accessible, based on memory activation deriving from the cognitive representation of the situation.

Most important, rather than being sequential, linear, and static, this entire process is cyclical, dynamic, and incremental. The cognitive constructs of “current state” and “current-state/end-state discrepancies” will be constantly shifting and evolving, based on changes in the context, listener feedback, and the speech being produced. Utterances are constructed incrementally, as cognition repeatedly cycles through sampling-activated information in memory, the contextual surrounds, and current-state/end-state discrepancies. Put differently, streams of truthful and deceptive discourse are not the result of a linear message production process; instead, this discourse is the result of a series of microbursts of cyclical mental activity among conjoined cognitive modules, the output of which is fed through consciousness incrementally to speech production.

### Propositions of IMT2

The 15 propositions that derive from this architecture range widely in focus. For example, Proposition 3 makes clear that “Because the same speech production system governs both truthful and deceptive discourse, no lexical differences exist between truthful and deceptive discourse.” Proposition 7 clarifies the following:

The comparative cognitive load associated with the production of truthful versus deceptive

discourse is not contingent upon the truth or falsity of the information units disclosed; but instead, is based upon the gap between information units activated within memory, the functional demands of the context, and the desired end state—that is, the difficulty of reasoning through the perceived problem space toward a viable solution.

Arguably, the three most controversial suppositions of IMT2 are the rejection of the widespread presumption that cognitive load is higher when deceiving than truth-telling; the notion that information difficulty (poorness of fit between truth and desired end states) drives deceptive discourse, rather than an a priori, top-down decision to deceive; and the rejection of “message” as a meaningful construct that exists anywhere in the production process.

IMT2 argues that in instances in which the truthful information is nonproblematic, truth-telling will generally occur. However, when truthful information is perceived as problematic, disclosing it in a way that achieves desired end-states will actually be more load-inducing than manipulating information. In fact, this is precisely why people manipulate information—because it is easier to do so. What’s more, the conscious “decision to deceive” actually occurs parallel to, or even after, the problem-solving module of the mind already has determined that the most efficient solution to the current context is manipulation of information. Finally, because incrementality in utterance construction is the norm for spoken discourse, at no time in the deceptive discourse production process does a unitary “message” (in toto) exist.

Although IMT2 did not posit specific hypotheses, the 15 propositions presented therein lent themselves to straightforward testing in ways that the authors judged to be self-evident. The authors currently are conducting a line of research testing these propositions.

In the insect world, the better the liar, the more likely that insect will live another day to survive, eat, and reproduce. In nature, lying and deception are essential to life.

Most often, deception requires higher cognitive processes than does honesty. According to P. Sadowski, deception necessitates an awareness of “other systems’ internal states.” In nature, however, deception most likely remains the result of natural selection and years of adaption instead of cognitive processes. In terms of natural selection, insects utilize deception as a form of defense for survival. Insects use deception in two main forms for survival and reproduction: camouflage and mimicry.

### Camouflage

Camouflage—also known as crypsis—provides insects the ability to blend in with their surroundings in order to protect themselves from predators. Various types of insects employ numerous methods of concealment and disguise based on their environment as well as natural selection. Some camouflage strategies include using markings to match the color and pattern of the background, while others require insects to change their color to match their background, allowing the organisms to blend in and remain hidden from predators.

While all camouflage serves to disguise insects from their prey, there are various and specific types of camouflage. According to M. Stevens and S. Merrilaita, there are six main types of camouflage: (1) background matching, in which the insect visually matches its surroundings; (2) self-shadow concealment, in which the creation of shadows is cancelled out by countershading; (3) obliterative shading, which obstructs an insect’s detection using a three-dimensional form; (4) disruptive coloration, in which the insect’s markings give the appearance of false edges and boundaries, which obstructs the recognition of an object’s true shape or form; (5) flicker-fusion camouflage, in which markings such as stripes confuse a predator by blurring the insect during motion and matching the insect’s surroundings; and (6) distractive markings, which direct the “attention” of the predator from traits that would give away the type of insect (such as the outline of the insect).

## Insects

From childhood on, society, storybooks, and fairy tales encourage children to “never tell a lie.” Young children and adults are taught to strive for trustworthiness through truth-telling and honesty and that lying results in distrust and hurt feelings. But in nature, a remarkably different story is told.

## Mimicry

While it is similar to camouflage, mimicry does not simply allow insects to hide from predators but instead allows the insect to look like another, less palatable insect or organism. According to *Merriam-Webster's Dictionary*, mimicry, by definition, is the insect's ability to imitate another organism or thing; it is a superficial resemblance of one organism to another, which provides protection from attack. For insects, mimicry serves as a swindle or a cheat to deter against predators.

Currently, there are three recognized types of mimicry: Batesian mimicry, Mullerian mimicry, and aggressive mimicry. In 1862, Henry Bates closely studied the phenomenon of insect mimicry and proposed that the model (the insect being mimicked) uses poisonous fluid or a stinger to deter prey. Bates posited that vulnerable or unprotected insects mimic potentially dangerous insects to deter and threaten predators, a concept more prominently known as Batesian mimicry.

Batesian mimicry holds that because of evolution, the insect that has the same shape or color as the toxic insect it is mimicking will deter predators because predators will have learned to avoid prey (through negative experience) that share the qualities of toxic or poisonous insects. For instance, *Cathedra serrate*, a saw-nosed plant hopper insect, will initially utilize camouflage and blend in with its surroundings, but if a predator persists in targeting its prey, the insect will reveal large red spots on its body that could be mistaken for the eyes of a larger animal, thus frightening the predator.

Another specific kind of mimicry known as Mullerian mimicry was coined by Fritz Müller in 1878. Mullerian mimicry exists when two or more poisonous species that may or may not be related mimic each other's warning signals. In this type of mimicry, all prey benefit because the predator needs only to be able to identify one type as unappetizing. This deception will then compel the predator to identify the rest of the mimicking insects as unappetizing as well because they all utilize the same color schemes and patterns.

Not only do insects use mimicry to deter predation, but adaptation has also allowed insects to practice mimicry in order to become better predators, a concept known as "aggressive

mimicry." With aggressive mimicry, insects share similar signals and traits as a harmless insect, which disguises them as harmless and unable to be correctly identified by their prey. Aggressive mimicry is in fact a direct contrast to defensive mimicry in that the insect strives to look innocent and harmless as opposed to toxic. Spiders (technically not insects), for example, are known for their displays of aggressive mimicry. Species such as *Argiope argentata* spin zig-zag patterns in the middle of their webs that reflect ultraviolet light, thus mimicking the pattern seen in many flowers. These patterns attract prey such as bees and other bugs.

Insects can also use similar forms of aggressive mimicry to avoid predation. Other forms of aggressive mimicry allow insects to attract a mate or to snag their next meal. For example, the female firefly of the genus *Photuris* will lure male fireflies by using flashing signals typical of other firefly species, luring the male closer to her in order to mate and subsequently devouring him. At the same time, the male species of this firefly has his own deceptive flashing technique with which he attracts the same females for mating.

Whether it is used to deter predators or attract mates, mimicry entails certain rules and guidelines. According to B. H. Purser, a mimicking insect must adhere to the following constraints in order to be effective: (1) The mimic must be more vulnerable than the model, (2) mimics and models must have easily identifiable color patterns and color schemes, (3) mimics and models must share the same habitat and region, and (4) models and mimics must possess similar behavioral patterns.

To mimic unpalatable prey, the mimic utilizes aposematic coloration, which includes blacks, yellows, reds, or oranges. These colors are often understood in nature as toxic or poisonous, which can deter predation. Moreover, it is important that mimics do not become overabundant in any given habitat because predators might not learn of their distaste for the insect, thus causing increased predation of mimic and model.

Insects not only use mimicry to visually imitate their model, but some insects have also developed the ability to audibly mimic their model as well. For instance, a syrphid fly not only looks like the yellow-jacket wasp that it mimics, but

The stick insect *Ctenomorpha chronus* (left), endemic to southern Australia, moves very little during the day, remaining in trees or bushes where they can barely be distinguished from the sticks surrounding them. A walking leaf insect in La Pura Vida, Costa Rica (right) mimics the shape and spots of the plants it eats. Mimicry allows the insect to look like another, less palatable insect or organism.

it can use its wings to mimic the sound of the yellow jacket's wings in flight. Additionally, Tiger moths are able to fool bats by tuning into the sounds that bats use to communicate and respond with their own ultrasonic sounds. The sounds that the Tiger moths emit might startle the bats as well as carry a message that deter bats from eating them.

According to B. H. Purser, clear differences arise when comparing insects that practice camouflage from insects that employ mimicry. For instance, insects such as grasshoppers, phasmids, and moths utilize camouflage because they spend most of their time in a sedentary state, while insects like flies and butterflies practice mimicry because they are often on the move. Sedentary insects must be able to blend in with their surroundings.

Some of the best examples of mimicry are exhibited by *Phasmatodea*, more commonly known as stick bugs. Stick bugs move very little during the day as they remain in trees or bushes where they can barely be detected or distinguished from the sticks surrounding them. Additionally, the walking leaf of Malaysia (*Phyllium giganteum*) uniquely mimics flora as it matches the shape and spots of the plants it eats. According to E. Bryce,

*Phyllium giganteum* has made very few changes for the past 47 million years and remains the largest of the leaf-like species.

## Insider Trading

Insider trading consists of the purchase or sale of a security, typically shares of corporate stock or options to buy or sell shares, while in possession of material, nonpublic information regarding that security. Although the precise legal definition of insider trading varies across different jurisdictions, in the United States the prohibition on insider trading generally encompasses only those transactions that involve a breach of a relationship of trust and confidence. For example, a corporate insider (such as an executive, employee,

lawyer, or accountant) who gains access to information that would significantly affect the value of the firm’s shares if made public would normally be under an obligation not to use that information to trade in the firm’s shares for personal gain.

Although not all transactions by corporate insiders in their firm’s shares are prohibited, those transactions that are not barred are typically heavily regulated and subject to specific disclosure requirements. In the United States, insider trading cases are generally prosecuted under the securities fraud laws. Thus, because deception sits at the conceptual core of what it means for conduct to be fraudulent, deception is often characterized as highly relevant to the concept of insider trading. However, this account—insider trading as a form of fraud—has been contested, in part because many forms of unlawful insider trading activities do not on their face seem to involve clear instances of deception. Consequently, some leading commentators have suggested that a property-rights account provides a more convincing justification for insider trading rules. A number of other scholars, meanwhile, have argued on economic grounds that the current ban on insider trading should be relaxed.

### Law and Legal Theories

The modern federal law of insider trading is complex. The law typically relied upon in most federal insider trading prosecutions is a general securities antifraud law, Section 10(b) of the Securities Exchange Act of 1934, and the Securities and Exchange Commission (SEC) Rule 10b-5 issued thereunder. Although the federal statute under which most insider trading prosecutions are brought dates to 1934, it was not until the 1960s that U.S. authorities began prosecuting insider trading claims in earnest. Rule 10b-5 prohibits “employ[ing] any device, scheme, or artifice to defraud,” or perpetrating acts which “operate as a fraud or deceit upon any person.”

In the shadow of this very general prohibition, several different theories of unlawful insider trading have been recognized by the courts. First, there is what is known as the “classical theory” of insider trading. Under this theory, as articulated in the U.S. Supreme Court case of *Chiarella v. United States* (1980), a person commits unlawful insider trading if that person purchases or sells

securities in violation of a fiduciary duty to the shareholders of that corporation. Such a corporate insider is under an obligation either to disclose his information or to abstain from trading. Thus, when that person buys or sells shares for his own benefit while remaining silent, he has (in a sense) deceived the shareholders of the corporation.

A second theory of insider trading that has been recognized by courts is known as the “misappropriation” theory. Under the misappropriation theory, a fiduciary obligation to the investors with whom the insider trades is not required; instead, the insider trader need simply breach a fiduciary duty (or fiduciary-like relationship of trust and confidence) to a third party (e.g., the source of the relevant, material, nonpublic information). For example, a journalist who breaches a fiduciary obligation to his employer in order to trade on material nonpublic information regarding Company X might be subject to the insider trading prohibition, even though that journalist had no preexisting fiduciary duty to the shareholders of Company X.

In addition to Rule 10b-5, a number of other insider trading prohibitions also exist. When the material inside information in question relates to an upcoming tender offer, an SEC rule known as Rule 14e-3 prohibits trading on that information irrespective of the existence of a fiduciary duty. In addition, section 16(b) of the Securities Exchange Act of 1934 requires certain corporate insiders to disgorge profits resulting from short-term trading in their corporation’s shares. Acts that constitute violations of the federal ban on insider trading may also violate other federal laws, such as the mail fraud, wire fraud, tax, or conspiracy statutes, and could also constitute violations of various state law prohibitions on insider trading.

Finally, deceiving authorities in the context of an insider trading investigation can also represent an independent basis for criminal prosecution. This latter risk was vividly demonstrated during the Martha Stewart case of 2002–03. Stewart, under investigation for allegedly selling approximately \$230,000 worth of shares of ImClone Systems on the basis of nonpublic information, was indicted and subsequently convicted of lying to federal investigators. (A related civil suit, in which the SEC alleged insider trading by Stewart, was settled in 2006.)

## Insider Trading Enforcement

The U.S. Securities and Exchange Commission describes insider trading enforcement as an important area of focus for the agency, and the SEC has in recent years brought between approximately 40 and 60 insider trading enforcement actions per year. Moreover, in the last several years, both the U.S. Department of Justice (DOJ) and the SEC have undertaken a number of particularly high-profile enforcement actions: for example, a series of prosecutions begun in 2009 implicated a number of prominent figures, including Raj Rajaratnam (a billionaire former hedge fund manager) and Rajat Gupta (a former McKinsey & Company executive and Goldman Sachs board member).

A particularly controversial issue relating to insider trading enforcement in recent years relates to allegations of possible trading on insider information involving members of Congress, congressional staff, and other government officials. Partly in response to these allegations, and out of concern for the perceived abuse of trust that such insider trading represents, Congress explicitly outlawed such trading in 2012 with the passage of the Stop Trading on Congressional Knowledge (STOCK) Act.

## Pros and Cons of Regulation

However, despite the current heightened enforcement climate, the desirability of insider trading laws as a policy matter has been vigorously contested. A number of prominent economists and legal scholars, beginning with Henry Manne in the 1960s, have suggested that the current ban on insider trading may not be justified on economic efficiency grounds. Manne’s critique of the ban on insider trading is twofold. First, Manne suggests that liberalizing insider trading rules should lead to more efficient securities pricing: permitting insider trading, it is argued, permits the market to discount all relevant information as soon as possible. A number of subsequent empirical analyses have supported this contention. Second, Manne argues that permitting insiders to trade on information might constitute an efficient mechanism for compensating those insiders. (This prong of Manne’s argument is somewhat more controversial and critics have raised a number of questions about its ability to be administered and other concerns.)

Other critics have suggested that aspects of the prohibition on insider trading are themselves deceitful—that notwithstanding its stated, public-regarding aims and goals, the ban on insider trading primarily benefits: (1) market professionals, who may be better situated to capitalize on share price movements when insider trading is banned, and (2) regulatory firms and agencies such as the SEC, which benefit from increased prestige and budgets as a result of the ban on insider trading.

As a general matter, a number of different justifications for insider trading regulations have been put forward. In early insider trading prosecutions, a theory of equal access to information was advanced. Under this theory, a key goal of insider trading regulations was understood to be ensuring that all participants in the stock market had relatively similar access to information; in effect, under such a theory, the goal was to prevent persons who engage in financial market transactions while in possession of material nonpublic information from profiting by “deceiving” trading counter-parties who might lack access to this information. By ensuring a “level playing field” among market participants, it was argued, basic fairness norms would be vindicated and investor confidence in the integrity of the financial markets would be promoted.

Yet this theory was criticized by some on the grounds that it was overinclusive and unrealistic: For example, in standard market transactions it is not necessarily required as a legal matter that both counter-parties have access to the exact same information, and the public generally does not regard it as inherently fraudulent conduct to fail to affirmatively disclose every conceivably relevant fact in certain other arms-length commercial transactions. Thus, even if one posited that the act of deception is in and of itself grounds for a ban on insider trading (irrespective of the consequentialist question whether insider trading harms others), in many cases it can be difficult to identify a clearly deceptive act in the absence of an affirmative duty to disclose on the part of the possessor of inside information. In part reflecting such concerns, the U.S. Supreme Court in two cases in the 1980s, *Chiarella v. United States* (1980) and *Dirks v. SEC* (1983), suggested that it disagreed with the notion that ensuring equal access to information among market participants

undergirded the insider trading prohibition. Instead, the court focused on whether the insider breached a preexisting fiduciary duty.

Other justifications for the ban on insider trading have focused on the harm that such trading can cause. Some accounts have focused on the potential role that insider trading might play in undermining investor confidence in securities markets. Critics of this argument have countered, however, by pointing to the experiences of certain foreign jurisdictions that combine highly successful securities markets with relatively low levels of insider trading enforcement. (Although the large majority of nations with developed securities markets ban at least some forms of insider trading, the level of insider trading enforcement varies significantly across different jurisdictions.)

Other commentators have defended the ban on insider trading by focusing on the potential harm of interference with corporate plans. For example, stock price movements that take place prior to an acquisition because of insider trading can consequently make the target more expensive and thus potentially frustrate those plans. A corporation that is attempting to assemble mineral interests that corporate insiders know to be particularly valuable might similarly find that the premature dissemination of that information via insider trading could frustrate those plans.

In addition, the deregulation of insider trading might, it has been suggested, create suboptimal incentives for managers: if insiders were permitted to trade on nonpublic information, those insiders might be incentivized to create more actionable information (including news that might adversely impact share prices) so as to maximize trading profits. Similarly, deregulating insider trading might create incentives for managers to keep information secret longer (thus increasing the window during which the manager might take advantage of trading on that information) rather than releasing that information to the investing public.

A final line of scholarly commentary suggests that deception—that is, fraud—should not be understood as sitting at the conceptual core of insider trading at all. Rather, it is suggested that protecting property rights in information should be the core justification for the ban on insider trading. In other words, insider trading should be

thought of as theft, not fraud. Thus, just as in the case of a ban on stealing trade secrets or infringing patents, the ban on insider trading might be understood as protecting efficient investment in information. Such an account has the benefit of explaining certain forms of prohibited insider trading in which the link to an affirmative act of deception might seem arguably tenuous.

## Intelligence

*Intelligence* is a broad term that can be used to describe aptitude in any of a spectrum of competencies (for example, spatial, musical, or interpersonal). Intelligence and intellectual capacity have been conceptualized a number of different ways; however, there are three categories of intelligence in particular that widely influence the ability to deceive and to detect deception: general intelligence, emotional intelligence, and social intelligence.

### General Intelligence

General intelligence addresses the brain's executive functions: the ability to think abstractly, plan, reason, and solve problems, among others. This is the form of intelligence that many intelligence quotient (IQ) tests measure. The executive

functions are primarily governed by the neocortex area of the brain, and evidence suggests that this region is a primary enabler of deceptive ability.

Across animal species, the development of the neocortex is correlated with increasing abilities at deception. In human children, the neocortex develops later than the rest of the brain, at around 4 or 5 years of age, and its maturation is a critical step in children's acquisition of deception skills. In imaging studies of adult human brains, the neocortex is highly active during the production of lies.

The brain's executive functions are taxed during deception because, compared with truth-tellers, liars must engage in more cognitive effort to create an utterance. Liars must remain aware of, but suppress, the truth while simultaneously fabricating a deceptive account that is plausible. Various models of lying behavior, such as the interpersonal deception theory and the activation-decision-construction model of lying, converge on the proposition that lying is harder on the brain than truth-telling.

In particular, the generation of a lie relies on certain aspects of executive functioning: inhibitory control and working memory. Inhibitory control is used to suppress behaviors that would indicate the truth or not support the deception attempt. Working memory is engaged in order to maintain awareness of both reality and the details of the lie being constructed. Studies of children suggest that weak executive functioning inhibits the ability to deceive at all, much less deceive skillfully.

Generally, research on executive function in children and lying behavior has been mixed. Research on young children has shown that those with higher executive functions may deceive more frequently. However, this may simply indicate the inability of children with undeveloped minds to conceptualize deception. Results from research with children (ages 4 to 16) who are old enough to conceptualize deception is mixed, with only some studies finding positive correlations between executive function and lying rates. A study of 8- to 16-year-olds found that those with higher executive functioning created more sophisticated lies but did not lie more often.

Not all lies are equally taxing. Some lies, such as those involving complex descriptions of reality, require more cognitive effort. Similarly, liars who are questioned by the lie recipient face greater

burdens on their cognitive ability, as they may have to come up with information and sustain an increasingly complex account. However, "white lies" may require less cognitive effort, and deception based on omission or equivocation is also less demanding. Liars who have time to prepare ahead of time also generate more convincing lies, presumably because thinking ahead can lessen the cognitive load. In situations where there are fewer demands on a liar's mind during the production of the lie, general intelligence is likely to be less helpful.

Various approaches to deception detection rely on measuring signs of the increased cognitive load experienced by liars; for example, the language used by liars may be necessarily vague and they may offer less information or fewer details. Liars may also take longer to respond. Putting liars in situations that increase cognitive load, such as asking them to recount events backward, increases the number of cues to deception in their behavior. However, it has not been tested whether individuals with higher executive functioning experience less cognitive burden and show fewer cues to deception. Paul Ekman notes that liars who are not clever or inventive may provide more of these "thinking cues," indicating they are fabricating information, but little work has been done to connect general intelligence and cognitive load while lying.

### Emotional Intelligence

Emotional intelligence (EI) involves skills related to emotional awareness and control. People with high EI are better than average at knowing and managing their own emotions. They are also able to read the emotions of others and make skillful displays of emotion.

Reports on those skilled in detecting lies suggest that the ability to accurately interpret others' emotions is a key part of their repertoire. High EI people working in professions in which lie detection is important, such as criminal investigation, perform better on tests of lie detection ability. High EI may enable better deception detection through increased aptitude in recognizing and interpreting partial or momentary expressions. These expressions occur as the by-product of emotions that liars, particularly in high-stakes situations, experience.

However, findings from laboratory studies linking emotional intelligence and deception detection are mixed. EI may increase the ability to detect and appropriately identify affective leakage, which can be interpreted as a sign that deception is occurring or even as a sign of the deceiver's true feelings. As such, studies have shown that high-EI individuals are better at detecting lies with an emotional component. Other research found that high EI was paradoxically associated with weaker deception detection skills in an emotional plea paradigm. This finding may be an artifact of the study design: high-EI participants may have attended to cues to deception, such as emotional turbulence and abbreviated statements, but misinterpreted them as signs of truth.

Emotional intelligence can be a useful tool in a deceiver's repertoire. The ability to display appropriate affect is important in lying for a number of reasons. An abundance of research on lie detection addresses nonverbal signals, particularly facial expressions, as hints to deception. Some of these nonverbal cues are under volitional control, and these in particular may be convincingly manipulated by high-EI individuals. While lying, high-EI individuals are able to feign emotions more convincingly than others. However, they are subject to baseline levels of emotional leakage. Other cues generated by liars, such as impressions of noninvolvement during discussion, may be managed by high-EI individuals through their superior control of expressiveness.

Emotion management is also important for deception skill. Emotions can overwhelm working memory and impair cognitive functioning. As noted earlier, certain situations and certain types of lies may be made more difficult with increased cognitive load. If high-EI individuals can manage the negative feelings associated with lying, they may have an easier time producing deception.

Display rules, which govern how people nonverbally express emotion, also involve elements of deception. Humans may need to minimize or exaggerate emotional expressions, mask them, or substitute one expression for another. The ability to skillfully present nonverbal emotional expressions may be of particular use when the nature of the deception is emotional (for example, feigning delight at a gift or jubilation at another's success). Being able to convincingly express false

emotion may also protect credibility. Court witnesses that display emotional expressions incongruous with their testimony are perceived as less credible.

### Social Intelligence

Although some definitions of emotional intelligence subsume social intelligence, it bears separate mention with respect to deception. A number of attempts have been made to measure social (or interpersonal) intelligence, for example, the Profile of Nonverbal Sensitivity or the Interpersonal Perception Task. Social intelligence is generally defined as an aptitude for understanding and interacting socially with other humans. It involves reading nonverbal behavior, relationships, and social situations accurately.

*Research on executive function in children and lying behavior has been mixed but has shown that among young children, those with higher executive functions may deceive more frequently.*

Some theories propose that human social intelligence is an adaptive trait that developed from deception and relationship management in primate groups. The Machiavellian intelligence hypothesis (also known as the social brain hypothesis) proposes that being able to skillfully manipulate and deceive other members of a group is an adaptive ability and, rather than tool usage or communication, is the primary evolutionary factor behind modern human intelligence. Research finds that primate species that have a larger neocortex, measured in volume relative to the rest of the brain, also engage in higher rates of intentional deception.

In human children, the development of the neocortex and associated executive functions coincides with the development of the social ability to understand other people's perspectives, which is sometimes called theory of mind (ToM). The development of ToM is a critical intellectual milestone for deception because it involves recognition of, and the ability to read, other people's mental states. Children with impaired cognitive and social functioning, such as fetal alcohol spectrum disorder, have serious difficulty in experimental tasks assessing ToM. In children with normal functioning, ToM is unrelated to general intelligence, but is associated with social intelligence.

According to models addressing interactivity in deception detection, such as interpersonal deception theory, social intelligence may allow for stronger performance by either the liar or recipient of the lie, particularly over time. As liars attempt to deceive, perceiving signs of suspicion, such as increased questioning on the part of the lie recipient, may lead to an adjustment in strategy. Other research positively correlates social skills with skill at lying in 11- to 16-year-olds, but this relationship attenuates with increased age in the study.

## Internet: Chat Rooms

Chat rooms are online conferencing environments in which multiple people are able to communicate with each other virtually. The broad use of the term *chat room* refers to both synchronous and asynchronous environments. For example, online forums or discussion boards are asynchronous virtual environments where people post messages at different times. Tools allow discussion threads to be extended indefinitely. Each person comments in response to the original posted comment and the other responses it has received. The dominant environment associated with chat rooms is a

synchronous online environment, in which conversation takes place in real time.

People “enter” and “leave” the virtual space of a chat as if walking in and out of a room. During a stay in a chat room, a person may participate in a conversation or simply “lurk.” Lurking involves reading other conversations but not joining in.

Chat rooms allow people to engage in focused discussion on a particular topic. The variety of topics is infinite. These can include support networks for medical or other personal concerns; real-time virtual worlds such as Moos, Muds, or digital gaming; social or political topics; or connecting with others in a social way. People from across the globe who share similar concerns, interests, and needs connect in these virtual spaces. Most people can find the tools necessary to create a chat to meet their needs if one does not already exist.

### **Security, Lying, and Deception in Chat Rooms**

People are typically required to register to join a chat room. However, some chat rooms may be exclusive and involve various levels of clearance. Some may require a mere sign-up with a nickname, e-mail, and password while others may require extensive verification of the person’s identity. In both synchronous and asynchronous environments, the rules of conduct are typically posted, and acknowledgment of agreement with these rules is required as part of registration. These rules are intended to promote civility in the appropriate cultural norms of the virtual environment as well as provide a sense of security for users.

Regardless of the level of purported security, people may mistakenly view their chat room experience as secure. The metaphor of a “room” used in the term *chat room* may bolster this mistaken sense of security. “Room” implies a misleading sense of privacy within an enclosed space away from the world outside; participants may feel secure because, while in a chat room, they are physically in an area of their choosing, often their own living space. Without the physical presence of others, there is a sense of anonymity afforded to online environments that produces a false sense of security. In addition, users are able to use monikers and avatars to hide their real identities. Therefore, despite the illusion of security, chat

rooms provide significant opportunity for deception and lying.

Discussion boards provide one such opportunity; the lurking aspect arises easily from the metaphor of “board” (i.e., blackboard). This idea suggests to the user that they can view posted information at their convenience. In contrast, synchronous, real-time chat rooms may be more conducive to lying and deception. Synchronous environments provide a voyeur-like opportunity for lurkers to read conversations without being visibly present to the others in the room.

Chat rooms are by their nature conducive to lying and deception. Chat rooms tend to involve strangers who may over time get to know each other better. However, they are not protected by the typical security of face-to-face communication networks. Even after long periods of time, people who have become virtual friends can be found to have lied about even the most basic information about themselves. Even seemingly obvious information such as age, home location, marital status, gender, or even the intent of a relationship can be fabricated when established virtually.

For example, love affairs occurring virtually through chat rooms can be found to be more complicated than face-to-face affairs. Unbeknownst to one of the people involved, these may eventually be found to be extramarital affairs, same-sex relationships, and relationships with considerable age disparities. In a chat room, the already fuzzy line between white lies and lies is blurred further. An innocent deduction of a person’s age in a face-to-face environment can be made more serious in a chat room because of the lack of external verification.

### **How Serious Is Lying and Deception in Chat Rooms?**

In some cases, lying in chat rooms is considered innocuous and commonplace. To solve the problem of a commonly used first name, people create inventive user names. In some cases, these are noticeable immediately as a lie. For example, someone might sign in as basketball star Jeremy Lin but, based on the content of his or her messages, obviously is not that person.

Other mild lying in chat rooms occurs when a user undertakes a new persona in the chat room environment, which the anonymity provided by

chat rooms enables people to do without being judged as severely as they would be in their non-virtual lives. In virtual world chat rooms, such as Moos and Muddst, creating a new identity is part of enculturation into the virtual world. In these environments, references to the world outside may yield negative attention from fellow members.

In other cases, researchers, journalists, and law enforcement professionals treading the ethical boundaries of their profession may lie about the reason for joining. For example, they may falsely claim a medical condition to join a medical chat. To justify their behavior, they might argue that they are entering the chat room for the greater good.

Trolling is a common practice in chat rooms. It involves the posting of deliberately provocative messages to a newsgroup or message board with the intention of causing maximum disruption and argument. Trolling involves deception if a person enters the chat room posing as someone other than they really are, such as a joiner with innocent intentions. For example, a troller may portray his or herself as holding an opinion consistent with the chat room but then make inflammatory comments against the goals of the group. In the most idealistic cases, trolling is undertaken to advance social, religious, or political causes. However, other users might view even this trolling as deceptive behavior.

In some cases, lying in chat rooms is considered more detrimental and consequential. It can even affect people outside of those virtual spaces. Lying in a chat room can be viewed as a violation of the norms of the group that can alter the emotional and social dynamics of the bonds created. Moreover, it can hinder the productivity of the group.

Criminal activity such as thievery and fraud are serious offenses that can begin with deception in chat rooms. Cybercrime costs billions of dollars each year. For example, romance scams involving chat rooms, dating sites, and social networking are reported to have incurred over \$50 million in losses in 2011, according to the Internet Crime Complaint Center. However, it is difficult to track and report cybercrimes, and cybercrime figures are said to be rough estimates at best.

Beyond the economic cost, however, is the human cost. Lying in chat rooms can result in aggressive and violent behavior that can extend

into nonvirtual space. Harassment, stalking, predatory behavior, child molestation, sex trafficking, and rape are among the most serious offenses that can also begin with deception in chat rooms. Predators use chat rooms to gain access to minors who might otherwise be inaccessible due to familial oversight. Bullying can involve fabricated stories about a victim and can extend beyond the virtual space. In some cases, bullying in chat rooms has led to suicide. On October 10, 2012, Amanda Todd, a 15-year-old Canadian girl, committed suicide after a disturbing Webcam chat with friends.

Internet privacy and protection acts often are limited by a narrow focus. This is especially the case for protections focusing on children (for example, the Child Online Protection Act and the Children's Internet Protection Act). Other protections have been the focus of objections on First Amendment grounds. Starting in 2004, Safer Internet Day has been celebrated each February. This provides a way to raise awareness about safety concerns and preventative strategies for Internet crime.

## Internet: E-Mail

Deception in e-mail can be divided into two broad categories: deception found in unsolicited e-mails, or spam, and deception in e-mail from known contacts, such as friends, family and colleagues. E-mail allows for some kinds of deception that are difficult in real life, but it also has properties that can make deception more easily detected.

### Spam

The most common form of deception in e-mail comes from unsolicited e-mails, or spam. Spam is often deceptive and involves a wide variety of scams designed to mislead the target of the e-mail. The most common deceptions involve misleading the targets to acquire their personal information and attempting to scam the targets into providing money. For example, one form of spam, called phishing, attempts to trick the target into believing that the e-mail is coming from a legitimate source, such as a bank. The target is then deceived into providing his or her account information. A common scam involving money is the 419 scam, in which a supposedly rich person, often from Nigeria, requests help from targets to get his or her fortune out of the country. In exchange for a small amount of money to help the person get out of the country, the targets are told they will get a large reward.

While deceptions that involve false identity representation in order to scam a target predate e-mail, e-mail has made it possible to attempt scams on a massive scale. The low cost of each e-mail makes the potential return for the spammer high and requires that only a fraction of targets actually respond to the e-mail.

### Deception in E-Mail Versus Other Media

E-mails from known contacts can also involve deception. One question that has been frequently examined is whether people lie more often in e-mail than in other forms of communication, such as the phone or face-to-face communication. One view is the social distance hypothesis, which argues that technologies like e-mail make people feel more socially distant from each other. This distance reduces negative feelings about lying, which should lead people to lie more in e-mails. A similar expectation focuses on the fact that

because there are fewer cues in e-mail, such as nonverbal and vocal cues, it should be easier for people to get away with lying.

Another view is to consider how specific features of e-mail affect the likelihood of deception. The Feature-Based Model points out three features that may change the frequency of lying in e-mail compared with face-to-face interaction: The synchronicity of the interaction refers to the degree to which messages are exchanged instantaneously and in real-time. A medium's recordability depends on the degree to which the interaction is automatically documented. The speaker and listener are distributed when they do not share the same physical space. E-mail is considered asynchronous: messages are not exchanged instantaneously; recordable: both parties retain a copy of the message; and distributed: people do not need to be physically near each other. Because of these properties of the Feature-Based Model, e-mail should have lower rates of deception in comparison with the telephone and face-to-face interactions.

Several studies have examined the question of whether e-mail changes how often people lie. The first study to compare e-mail with other media asked people to record all their lies over the course of a week. People reported lying at least as often in e-mail in comparison to telephone, instant messaging, and face-to-face interactions. The data pattern fit the predictions from the Feature-Based Model. In a follow-up study, e-mail again had the fewest lies, but e-mail contained the most explanation lies. Because of the asynchronous nature of e-mail, writers had more time to construct sound explanations that could withstand the potential scrutiny associated with a recordable medium.

Another study presented people with scenarios that required lying in a business context. People in the study chose which media they would be most likely to use to lie. Regardless of the severity of the lie or familiarity of the target, a face-to-face interaction was the first choice for executing the deception, followed by telephone and e-mail.

Other studies have examined how e-mail might affect deception with a stranger. Because the asynchronicity of e-mail allows a person to delay his or her replies, senders may be more inclined to lie about their feelings to strangers. One study examined the frequency of deception when getting to

know a stranger face-to-face or using text-based communication similar to e-mail. E-mails contained five times as many lies as people speaking face-to-face. This study highlights that when engaging strangers in an online context (for example, online dating), deception can occur more often than in face-to-face communication.

When e-mail was compared with pen-and-paper communication, a study found that people are more willing to lie when communicating via e-mail than via pen and paper. People felt more justified to lie online. In the pen-and-paper condition, participants had a common notion that written documents carried more permanence and legal consequences than e-mails. People also felt more anonymous online, even when it was not objectively the case. Features of e-mail can trigger different psychological cues concerning appropriate behavior and consequences.

The importance of the permanence of e-mails is illustrated in the case of a scandal involving General David Patraeus, in which Patraeus, the director of the Central Intelligence Agency (CIA) in 2012, was investigated for having an affair with his biographer Paula Broadwell. The investigation involved data from e-mail that Patraeus and Broadwell used to communicate with one another. They used a technique in which Patraeus would log into an e-mail account and write his message in a draft. Broadwell would later log into the same e-mail account, read the draft, and then delete it. In this way, no messages were technically sent. The draft, however, was cached and available for investigation.

The recordability of e-mails also makes it possible to analyze them to determine whether there are linguistic cues to deception in these messages. Several studies have found that deceptive e-mails have more words than truthful ones, perhaps because e-mail allows greater time for editing. Deceptive e-mails also include fewer self-references, like “I,” “me,” and “my,” but more other-references, like “you,” “he,” and “she.” Finally, deceptive statements in e-mail also contain heightened use of emotional words, especially words conveying negative emotions. These linguistic cues are not always indicative of deception, but are trends in the linguistic pattern of deception.

Deception in e-mail will continue to evolve as more people adapt and gain experience with

this medium. Deception in the form of spam is likely to persist, with deceptive tactics designed to acquire personal information, such as passwords, credit card details, and Social Security numbers. Deception in e-mail from known contacts is also likely to evolve over time. While it is difficult to gauge intent with linguistic analyses, researchers have been able to find several promising associations between language patterns in e-mail and deception.

## Internet: E-Mail Scams

Several high-profile deceptions have used e-mail as a medium, including the Nigerian (419) scam and the advance fee scam. One of the most prevalent is phishing, which refers to an attempt by deceivers to solicit private information from individuals by posing as a legitimate company. The request is transmitted via a computer-mediated message (frequently e-mail) and often employs social engineering methods to dupe the message recipient. Security experts estimate that businesses and individuals experience over \$2 billion in losses a year globally because of phishing efforts.

### Phishing

The homonym “phishing” is a metaphor for a technique often used by deceivers, the “bait and hook” technique. In this context, the bait is the message itself. Most commonly, the message describes an urgent problem that the recipient must address by divulging private information, such as account usernames and passwords, credit card numbers, and Social Security numbers. The message supplies recipients with a hyperlink to a falsified Web site (the “hook”) that allows its visitors to enter the desired information, essentially resulting in identity theft. Some of the counterfeit Web sites are instructed to surreptitiously install spyware, like keystroke loggers, on the recipient’s computer.

Phishers engage in deceptive techniques in appearance, content, and architecture of their messages to improve their chance of success. The e-mail message and the associated Web site commonly contain elements that aid in their appearance of legitimacy, such as logos, slogans, and word marks used without the permission of the authentic company. The core of the e-mail message itself describes a fabricated problem or event, and it is often accompanied by deceptive phrasing intended to encourage the recipient to take a rash course of action. This includes social engineering tactics like adding an element of urgency needed for a response (in order to avoid dire consequences resulting from the fabricated problem), or promising the message receiver a prize for responding.

Finally, phishing Web sites tend to be extremely temporary in nature, only existing on a remote

Web server for a few days. Their fleeting nature necessitates a provisional uniform resource locator (URL) and fictitious return e-mail address. Phishing messages and Web sites tend to lack digital signatures or certificates of authentication, and Web sites are most likely to be registered using a “subdomain” hosting account, with the co-opted company name appearing beneath the top level domain in the URL hierarchy. In some instances, legitimate Web sites have been hacked and hijacked in order to exploit the Web site’s authenticity for URL-naming purposes.

In terms of the deceptive communication between the phisher and the target, phishing attacks are rarely accompanied by repeated or prolonged interaction. The attack is limited to a single message requesting a response, and phishers do not commonly reply to requests for more information about the problem. However, phishers are able to employ mass e-mailing (spamming) as a method for initiating contact with multitudes of people at no additional cost. Message recipients are chosen at random, either through lists of valid e-mail addresses that have been collected using automated search agents (spiders or Web crawlers), or by attempting to send messages to random strings of characters representing the e-mail usernames on a particular domain. Phishing attempts have been observed to target tens of thousands of potential recipients at a time.

While a number of technical countermeasures have been introduced to reduce the success rate of phishing attacks, such as network filtering and antiphishing toolbars for Web browsers, the decision to respond to a phishing message is ultimately in the hands of Internet users. Security consultants have advocated educating users on the methods employed by phishers and other online scam artists. Experienced Internet users have been observed to be better equipped at detecting phishing attempts, often by noticing suspicion-raising cues, from misspelled words and poor grammar that would be unexpected from legitimate companies to the implausible circumstances described in the message. Advocates suggest that e-mail users resist the urge to respond to any unexpected requests for information without first contacting the purported requestor independently.

An allegedly fraudulent check in an Internet scam, sent by a "buyer" (scammer) to a target (a seller of a piano on Craigslist) to buy the item plus moving expenses. The target deposits the check, thinking the money is in his or her account, then wires money to the supposed "movers" (the scammer's account). However, the check bounces, the "movers" never show, and the victim is cheated.

### Nigerian (419) Scam and Advance Fee Scam

The Nigerian (419) scam (so named for the International Exchange Code of the country from which many of these efforts originate) uses e-mail as the method to contact unsuspecting Internet users about rendering aid to an official of a foreign nation. The message usually describes a legal entanglement involving the now-deposed official who needs assistance in retrieving large amounts of money from his or her homeland, which is now beyond his or her reach. The message recipient is offered a percentage of the overall fortune in exchange for funding the legal fees required for withdrawal. The entire scenario is fabricated, with the target of the scam being victimized for the sum of all the fictitious fees. Unlike phishing, the 419 scam artists have repeated e-mail interactions with their victims, sometimes lasting for years.

Other deceptive scams using e-mail include the advance fee scam, which involves an e-mail touting an offer for a preapproved credit card, with the only caveat being an initial sign-up fee that the message recipient must pay in order to start the credit account. Lottery scams involve the message recipient being notified about winning a large monetary prize from an international lottery. Much like the 419 scam, the winnings can only be wired to the recipient following the advance of a fee needed to process the delivery. As with phishing, the detection of the deceptive nature of these

messages requires a methodical appraisal of the content by the recipient.

# Internet: Facebook and Social Media Sites

Social media are defined by *Webster's Dictionary* (2012) as Internet-based forms of communication, such as Web sites for social networking and microblogging sites, through which users create online communities to share information, ideas, personal messages, and other content (for example, photos and videos). Among the popular social media sites are social networking sites such as Facebook and LinkedIn, video-sharing sites like YouTube, and the microblogging site Twitter.

## Deception Online

Deception, defined as intentionally relaying messages to elicit an inaccurate belief, ranges from complete fabrication of information to concealment, partial truths, and vagueness. Large-scale studies have differed in the frequency of online deception. After observing text-based communication for several years, P. Curtis noted that individuals' misrepresentation online was uncommon. R. J. Rotunda and colleagues found that only 11 percent of participants in their sample lied about age, job, or gender on the Internet. Higher levels of online deception were reported by M. T. Whitty, including 65 percent of participants lying about their age, 49 percent lying about their occupation; 36 percent lying about income, 32.5 percent lying about their education, and 23 percent lying about their gender.

More recently, B. Cornwell and D. C. Lundgren found that among their participants, 27.5 percent misrepresented their physical attractiveness; 22.5 percent provided an inaccurate age; 17.5 percent provided incorrect background information regarding their education, occupation, and home life; and 15 percent distorted their hobbies and religious beliefs. However, because of the tendency for offline friendships to lead to Facebook friendships, the likelihood for deception in social networking is likely considerably lower relative to general online environments. This method of friendship acquisition via social networking creates accountability for the user, which lessens the likelihood of dishonesty in social media self-presentation.

## Self-Presentational Manipulation

Liars seek to meet a variety of goals by interacting deceptively with others. Most of these goals can be categorized as either overt or covert task goals. Overt goals comprise the self-presentation component of deception. This means that the intention is to publicly present a certain, desirable—albeit dishonest—image of oneself. Furthermore, according to R. S. Feldman and colleagues, a heightened sense of self-presentation resulted in more lying in order for individuals to accomplish that goal. Obtaining covert goals focuses individuals on the deception itself, and they usually hide their goals from the audience.

Regardless of the goal, those individuals who engage in deception will have a cognitive or affective response to the behavior. This reaction can range from guilt or discomfort to duping delight. Extending this research to social networking online, profile manipulation occurs when individuals alter their profiles to present a certain representation of themselves. These self-presentational behaviors can range from untagging unflattering pictures, to showcasing a more attractive version of an individual, to disclosing personal information tailored to portray the type of person the user wishes to be. Also, the mere utilization of privacy settings (for example, showing certain information to designated people) is a way of self-presenting in social networking and has been shown to influence viewers' perceptions of that user and lead them to make inferences about offline activity. Therefore, deception in social networking not only involves the crafting of information to create desired impressions but also the availability to access specific types of information the user allows.

A well-established point of view, referred to as idealized virtual-identity, holds that online social networking profiles are constructed to portray an idealized sense of self that is incongruent with the actual self. In direct opposition to this opinion is the extended real-life hypothesis, which maintains that online profiles are accurate extensions of a person's real life. This hypothesis is based on the difficulty with which one could deceive in an online social network. The lack of control in representing an idealized version of the self on social networking sites (for example, wall posts or comments on a photo), and the interactivity between

social networking users providing a sense of accountability, suggest that online profiles are indeed generally accurate extensions of a person.

M. D. Back and colleagues conducted a study to determine which of these perspectives were supported empirically. They examined self-reports of personality, friends' opinions of the participant's personality, and the Facebook profile of the participant in a sample of young Facebook users from the United States and Germany. Their results showed consistency in the three sets of measures and a lack of idealization in online portrayals of the self, which supports the extended real-life hypothesis. These results again support the notion that deception in Facebook and social networks is relatively low.

There are also notable gender and personality differences with regard to the type of deception individuals engage in, as well as the purpose. Although an equal number of men and women use Facebook, more men use the site for dating and acquiring new information than women. Research indicates that men tell more self-oriented lies than women. This supports the idea that men are more concerned with self-promoting in interaction, while women are preoccupied with affiliation motivations. Based on this, it is possible that men are more likely to engage in deception in online social networking because of their motives for use.

Despite many obstacles involved in self-presenting oneself more positively than the genuine self, narcissists tend to overlook the boundaries of accountability and deceive more on Facebook than others. Furthermore, Jolene Zywicki and James Danowski showed that introverts possessing low offline self-esteem attempted to manipulate their profiles to obtain greater popularity by untagging themselves in unflattering photos and carefully crafting their profiles to appear desirable and trendy. Thus, although deception in online social networking is not as prevalent as in other forms of online interaction, deception is employed by certain individuals who are motivated to do so.

impressions among their audiences. For example, someone on a date may want to appear likeable and/or successful. A man may accomplish this by arriving on time, being well dressed, and carrying flowers for his date. When the communication mode changes to the text-based chat via the Internet (or computer-mediated communication [CMC]), other situational factors influence the ways individuals self-present. For instance, in a text-based situation (for example, e-mail), one's signature is the best way to convey status; the use of emoticons may be the best way to convey likeability. The combination of physical distance and relative anonymity available in CMC may foster more deceptive self-presentation.

### Deceptive Self-Presentation

People self-present and exaggerate or even fabricate traits or skills to create their desired impression. The probability of disingenuous self-presentation increases when the pressure to self-present is high. Interacting with a member of the opposite sex, particularly an attractive one, increases motivation to self-present.

These and other patterns of deceptive self-presentation have been observed in dating contexts. It is more common for men to self-present to desirable potential dates than it is for women, according to research by W. C. Rowatt and colleagues. Research also shows that men and women deceptively exaggerate different characteristics in the context of online dating. In research published in 1991, W. Took and L. Camire asked college students to indicate their willingness to attract a mate using deceptive self-presentation. Men were more willing to use deception to appear dominant, resourceful, and kind. Women were more willing to present their physical appearance as more desirable than it actually was. Overall, the research on dating deception indicates that both the situation and gender of the self-presenter impact the outcome.

## Internet: Online Dating

Self-presentation, also called impression management, is typically used to achieve specific goals. The self-presentation process is integral to lying and deception in online dating. Through this process, individuals attempt to create specific

### Deception Online

There are many differences between CMC and face-to-face (FTF) communication. These differences fit into four general categories: relative anonymity, reduced importance of physical appearance, attenuation of physical distance, and greater control over the time and pace of interactions.

The most relevant to a consideration of online dating deception is the relative anonymity present in many forms of CMC. Being relatively anonymous in an online social interaction can reduce accountability and may produce depersonalization and deindividuation in the online interactants. Thus, anonymity enhances the probability of behavior such as deception.

Also germane to online dating deception is the decreased importance of physical appearance online. This may also likely increase deception because people can claim to look like whomever they want. The decreased focus on nonverbal cues relative to FTF interactions may also facilitate greater use of deception, as the lack of nonverbal cues produce a feeling of anonymity in people. The greater control over the time and the pace of CMC interactions is also relevant to dating deception, as this feature of CMC enhances selective self-presentation online. Overall, the features of CMC reviewed above each contribute to a greater likelihood and opportunity for individuals to engage in deception in online situations such as dating.

### **Deceptive Self-Presentation in Online Dating**

Dating Web sites—Web sites specifically designed to match up people looking for romance—is rapidly increasing as a means of finding dates. To join a typical online dating Web site, a person registers and fills out a profile, including demographics, desired mate preferences, and sometimes personality measures. A photograph provided by the online dater can be included with the profile if she or he chooses. Initial contact between prospective daters occurs via messages sent by the dating Web site to ensure confidentiality. If initial conversations progress in a promising manner, telephone and/or face-to-face contact will follow.

Research on people using online dating Web sites shows that some online daters present unrealistic or deceptive profiles. G. J. Hitsch and colleagues found that online daters exaggerated in their profiles in a specific pattern: men emphasized their wealth and status, while women emphasized their physical attributes. Another study indicated that men reported they were taller, while women reported that they were thinner. Participants also

reported being accurate in the photographs and relationship details they provided. Overall, the emerging online dating research indicates that online daters will engage in deceptive self-presentation, but if they do, they balance their deception against the possible by the promise of a future interaction.

R. E. Guadagno, B. M. Okdie, and S. Kruse examined how differences in communication modes and expectations about meeting a prospective romantic partner impacted the degree of deceptive self-presentation displayed within the context of dating. To examine this, participants filled out personality measures at two time points. The first was to obtain baseline personality information. Next, participants were randomly assigned to one of four anticipated meeting conditions: face-to-face, e-mail, no meeting, and a control condition with no pretense of dating. Compared with baseline measures, male participants increased the amount of exaggerated self-presentation when anticipating a future interaction with a prospective date, but women did not. Specifically, men emphasized their positive personality characteristics more if the meeting with the potential date was more anonymous (for example, a CMC meeting) compared with a less anonymous condition (for example, a FTF meeting) or the control conditions. Women did not exaggerate their characteristics between the two time points, regardless of condition.

The results of the study by Guadagno and colleagues fit well with the literature on mate selection. For instance, L. A. Jensen-Campbell, W. G. Graziano, and S. G. West found that women preferred to date men who were helpful, particularly when they were both helpful and dominant. Additionally, research on personality and mate preferences indicates that newly married women perceive their husbands as being very likeable. Thus, the limited evidence suggests that women may differentiate on personality more so than men when selecting a mate.

Second, the online dating research indicates that women get more contacts through online dating than do men. One study indicated that 57 percent of men versus 23 percent of women never got a single e-mail from a prospective date. This is likely because human mate selection is one of female choice, so men approach women through

these online dating sites more often than women approach men.

## Interpersonal Deception Theory

Interpersonal deception theory (IDT) is a mid-range theory developed by David Buller and Judee Burgoon to predict and explain the process of encoding and decoding deceptive messages in interpersonal encounters. In response to what the authors perceived as an overly psychological orientation in the social science literature on deception, Buller and Burgoon created an interpersonal communication perspective on deception. Their theoretical framework articulates assumptions about interpersonal communication and deception and empirically testable propositions about deception as a communicative activity. The original articulation of IDT included a network of general and interrelated propositions from which hypotheses could be generated. These general statements are meant to be probabilistic, in light of the multiple and sometimes offsetting factors that influence a given deceptive episode. Subsequent descriptions and revisions by Buller and Burgoon further clarified and reworded the relationships specified by the propositions.

The scope of the theory is confined to interpersonal interactions and ones in which communicator credibility is salient. Self-delusion, role-playing, unwitting or inadvertent transmission of false information, discoveries of another's deceit outside interpersonal encounters, and nonhuman deception all fall outside the intended scope of the theory. As defined within IDT, deception refers to messages or signals knowingly and intentionally transmitted to foster a false belief or conclusion by another. The emphasis on messages does not deny that humans and other species mislead conspecifics in myriad noncommunicative actions nor that regularities gleaned from noncommunicative actions and nonhuman signals may help inform the causal mechanisms undergirding interpersonal deception.

### Assumptions of IDT

Whereas many theories about deception focus on what an individual experiences or expresses, IDT as a communication theory emphasizes what happens between people rather than within people. Among the central communication-relevant assumptions of IDT are that communication is an

interdependent activity and that both sender and receiver are active parties to the construction of deceptive interchanges. Interdependence implies that receivers influence sender cognitions and behavior, and vice versa, making deceptive signals not just the product of what the sender is experiencing but also how an interlocutor's communication affects the sender. Receivers also are not passive recipients of whatever signals are expressed by senders but instead play an active role, such that their emotions, cognitions, and communication warrant as much attention as those of senders. Receiver suspicion is an important factor when analyzing deceptive exchanges.

Another assumption is that, like other forms of communication, deception and its detection are goal-driven and often strategic (deliberate); deceivers and receivers act to accomplish such goals as protecting self, fostering a favorable image, preserving the interpersonal relationship, creating a comfortable interaction, or achieving instrumental aims. Deceiver and receiver's verbal and nonverbal communication reflect strategies and tactics to achieve those ends, even though like other intentional but routinized communicative acts, they may be "run off" without much conscious awareness.

Telling ingratiating white lies is an example of deceit that is produced easily and satisfies multiple communication goals, from preserving the relationship and saving another's face to promoting liking. Receivers may similarly enact covert and nonobvious strategies to ascertain a sender's truthfulness so as to minimize sully the relationship with evident suspicion, or they may do the opposite, "ambushing" a sender with direct accusations to catch the person off guard and expose the truth. IDT assumes that many communication strategies and tactics are overlearned and performed relatively effortlessly. Deceit as a special case of interpersonal communication should therefore exhibit strategic activity.

However, overlaid atop the usual communication goals will also be the goal of avoiding detection, which may instigate additional strategies and tactics for gauging deceptive success. The additional communicative demands imposed by deceit or its detection may produce "nonstrategic" activity, actions that create disruptions of normal communicative patterns and betray emotional and

cognitive states different from what the sender or receiver intends to project. Thus, IDT makes some assumptions about deception itself, including that it may elevate arousal, activate certain emotional states, and place more demands on memory and cognitive processes, much as early psychological theories proposed.

For example, producing false and misleading messages requires first mentally accessing what is truthful, then mentally editing and reformulating that “reality” into untruths that meet criteria of plausibility, consistency with known facts, and consistency with previous messages. However, some truths are more difficult to tell than lies, not all deception creates negative arousal and emotions, and not all deception is challenging to produce. IDT thus does not subscribe to the view that deception inevitably differs from truth or produces telltale, involuntary signs. Also, by characterizing deception as a social rather than psychological phenomenon, IDT embraces the view that deception-induced emotions, mental challenges, and arousal can be masked, exaggerated, attenuated, and otherwise managed so that outward expressions lack a one-to-one correspondence with what is experienced internally and do not constitute clear signals of deception. The potential mismatch between what is felt and what is displayed remains a point of controversy in the research and theorizing about emotions.

One last assumption is that interpersonal deception is a dynamic activity such that behavioral patterns fluctuate over time as sender and receiver adapt to one another’s verbal and nonverbal messages and feedback. “Snapshots” of deception at one point in time may bear little resemblance to deception at subsequent junctures within the same interpersonal interaction or across interactions and cannot be validly generalized to them without knowing the context in which they appear and the behavior of other interlocutors.

The assumptions associated with IDT are not meant to be tested but instead act as theoretical primitives that provide the “glue” holding propositions together. What are tested are the hypotheses derived from the propositions themselves.

### IDT Propositions

Propositions are general statements that specify an interconnected system of relationships among

the key terms in the theory. Below are the updated, reordered, and merged propositions. A schematic of the theoretical model appears in Figure 1.

*Proposition 1.* Contextual features of deceptive interchanges that systematically influence sender and receiver cognitions and behaviors: two of superordinate importance are (1) the interactivity of the communication medium and (2) the demands of the communicative task. *Cognitions* is shorthand for internal states and encompasses emotions as well as thoughts. Both the internal states and externally manifested behaviors associated with deception are said to be influenced in predictable ways by salient features of the communication context and interpersonal relationship. Two that are proposed to be highly salient are whether the medium in which communication takes place is interactive or not and how demanding the communicative task is. Research evidence indicates that when sender and receiver carry on a back-and-forth dialogue, with more access to social cues and producing utterances on the fly, it benefits deceivers more so than receivers, whereas having to talk without benefit of receiver feedback (e.g., giving a lengthy monologue to a listener or using an asynchronous, computer-mediated communication medium like e-mail) can impair sender communication and make deception more detectable by receivers. Likewise, informal discussions are less demanding than formal interviews and benefit sender deception more than receiver detection.

*Proposition 2.* Relational features of deceptive interchanges systematically influence sender and receiver cognitions and behaviors; two of superordinate importance are relational (1) familiarity and (2) valence. Degree of acquaintanceship and positivity or negativity of the relationship can make deception easier or more difficult. The same is true for detection.

*Proposition 3.* Truthfulness and honesty are more expected with (1) more interactive contexts and (2) greater relational positivity between sender and receiver. People are more likely to be truth biased (overestimate others’ truthfulness) when interacting with, rather than observing, another or when communicating via noninteractive media, and when interacting with those they like and admire.

*Proposition 4.* A deceiver's fear of detection is positively influenced by (1) how familiar the receiver is with general deceptive behavior or (2) information about the sender; it is inversely related to (3) a receiver's expectations for truthfulness and (4) how relationally familiar (acquainted) the receiver is with the deceiver. Deceivers are less fearful of being detected if they think receivers expect them to be truthful and if receivers are strangers, lack knowledge about them, and/or are unfamiliar with the sender's usual communicative behavior and unfamiliar with deception signals.

*Proposition 5.* Over time, interactive contexts heighten strategic activity and lessen nonstrategic activity (arousal, negative or dampened affect, reduced involvement, and performance decrements). Much deception research has taken place in noninteractive contexts. IDT proposes that when deception occurs under interactive conditions, deceivers

will exhibit more strategic activity (e.g., improving message content and linguistic style, employing more believable and normal nonverbal behaviors, and fostering a more credible overall demeanor), especially over time, as they come to repair any initial missteps. At the same time, typical telltale signs of deception will be reduced.

*Proposition 6.* Target benefit alters strategic and nonstrategic activity during deception such that compared to deceiving for others' benefit, deceiving for self-gain (1) prompts more, and qualitatively different, strategic activity; and (2) prompts more nonstrategic behavior associated with concerns over detection and increased strategic activity to avoid detection. Deception can be undertaken for selfish or altruistic reasons. IDT proposes that when the deception benefits self, deceivers will exert more effort to control their verbal and nonverbal messages but will also show more telltale signs

**Figure 1** Model of interpersonal deception theory showing antecedent and interaction factors that affect the outcomes of perceived success and detection accuracy.

Source: Burgoon, J. K. and D. B. Buller. "Interpersonal Deception Theory. In *Readings in Persuasion, Social Influence and Compliance-Gaining*." J. S. Seiter and R. H. Gass, eds. Boston: Allyn & Bacon, 2004.

of deceit. When the deception benefits others, the communication will more closely resemble truth in that it will lack such strategic activity as overly detailed content, overly contained behavior, and inauthentic pleasantness as well as lack the nervousness, negative affect, and speech dysfluencies often associated with deceit.

*Proposition 7.* Deceiver motivation to behave strategically is (1) inversely related to projected receiver expectations for truthfulness, (2) positively related to relational familiarity with the receiver, and (3) positively related to deceiver skill. A deceiver will try harder to behave in a credible fashion if they think the receiver is suspicious of what they are saying. A deceiver will try less hard if they think the receiver expects them to be truthful. Motivation will also be higher if deceivers and receivers are well acquainted. Finally, motivation and strategic behavior are related to social skills. Some deceivers have more communication skills than others. More skilled individuals will attempt to exhibit more strategic activity and to suppress nonstrategic activity.

*Proposition 8.* A receiver is more likely to judge sender as credible when (1) the context is interactive, (2) sender is a skilled communicator, (3) receiver is truth biased, and (4) sender's communication conforms to expected patterns. In interactive contexts, communicators are more likely to establish common ground and give each other the benefit of the doubt, thus regarding each other as believable and truthful. More skilled senders will also be more believed, especially by truth-based receivers and when senders behave in expected ways.

*Proposition 9.* Receiver detection accuracy is directly related to (1) deviations of sender communication from expected patterns, (2) information familiarity, (3) behavioral familiarity, and (4) receiver decoding skills and inversely related to (1) context interactivity, (2) receiver truth biases, and (3) sender encoding skills. A receiver is more likely to detect deceit if the sender's communication is deviant (unexpected), the receiver has some relevant information about the sender, or the receiver knows either the sender's usual communication patterns or more general, reliable

clues to deception. A receiver is less likely to detect deceit to the extent that the communication context is interactive between sender, the receiver holds strong truth biases, or the sender is a skilled communicator. Although IDT proposed that receivers who are more skilled decoders should also be better at detecting deception, the empirical evidence has not supported this claim.

*Proposition 10.* Receiver suspicion produces changes in receiver strategic and nonstrategic behavior. Like senders, receivers may also adopt deliberate communication strategies (e.g., establishing rapport to take deceivers off guard) but may also inadvertently give off unintentional telltale signs of their skepticism.

*Propositions 11 and 12 (merged).* Senders perceive suspicion when receivers (1) are actually suspicious, (2) engage in communication that deviates from expected patterns, (3) signal disbelief or uncertainty, or (4) probe for further information. Senders often sense actual suspicion by receivers but also may perceive it to be present based on various communicative behaviors of receivers. Research evidence supports both.

*Proposition 13.* Suspicion (perceived or actual) evokes changes in both strategic and nonstrategic behavior by senders. Deceivers faced with real or imagined suspicion attempt to repair their performance through strategic activity but may also display inadvertent nonstrategic behaviors.

*Proposition 14.* Deception and suspicion displays change over time. In keeping with the assumption that deception is a dynamic enterprise, this proposition posits that the verbal and nonverbal displays of both deceptive senders and suspicious receivers should vary over the course of an interaction. Several studies have confirmed the deception part of this proposition; little research to date has looked at suspicion patterns over time.

*Proposition 15.* Reciprocity is the dominant interaction adaptation pattern between senders and receivers during interpersonal deception. Deceivers and their targets will primarily reciprocate one another's behavior, resulting in

interactions that look much like nondeceptive ones. This partially explains why deceivers are often successful in evading detection.

**Proposition 16.** Terminal judgments of sender credibility and receiver detection accuracy are a function of (1) most recent receiver cognitions (suspicion, truth biases); and (2) most recent sender behavioral displays. Given that deceptive episodes are dynamic events, with behaviors and cognitions fluctuating throughout, this proposition says that receivers' final judgments and detection accuracy are strongly influenced by their most recent cognitions and behaviors, that is, by recency rather than primacy effects.

**Proposition 17.** Senders' perceptions of deception success at the conclusion of a deceptive episode are a function of (1) whether receivers appear suspicious and (2) their most recent behavioral displays imply belief. Put differently, senders judge their own success by whether receivers' suspicions appear to be allayed and receiver behaviors imply they are accepting of senders' communication.

### Critiques of IDT

Early criticisms of IDT centered on the fact that it did not offer a single explanatory mechanism, that some of the propositions did not state directional relationships (for example, increasing or decreasing), that deception could instead be characterized as a persuasive activity, and that some of the experiments supporting IDT had flaws. Burgoon and Buller responded that the theory was not meant to advance a single explanatory mechanism but instead to fit a broad communicative perspective on the phenomenon and to include multiple causal mechanisms that fit a general interpersonal communication account of the process. They agreed that some propositions were nondirectional but intentionally so because they were meant to specify functional relationships. They also agreed that a persuasion account was consistent with their view of deception as a strategic activity.

The extent to which interactive deception differs from noninteractive deception and whether deceivers attempt to repair their communication in the face of suspicion remains contested. Newer self-presentation perspectives on deception embrace some of the strategic aspects of IDT, if not its other

tenets. Research testing many of the IDT propositions is ongoing and is extending it into mediated and human-computer interaction contexts.

## Invention of Lying, The

*The Invention of Lying* is a 2009 comedy starring British comedian Ricky Gervais, who also cowrote, codirected, and coproduced the film. The movie presents a fantastical world in which Gervais's character is the first person with the

ability to lie and deceive others. The film is a morality play about the use of deception in the world. Some also consider it a proatheism story, as the world without lies also lacks religion until Gervais's character creates God through his lies. Though neither a critical nor commercial success, *The Invention of Lying* offered an innovative look at how lying affects everyday interactions.

### Plot Summary

Mark Bellison (Gervais) lives in a world in which no one has ever told a lie. He is short and chubby, and because everyone tells only the truth, people do not hesitate to remind him of his shortcomings. When he goes on a blind date with Anna (Jennifer Garner), she informs him that she is unimpressed with his lack of money and attractiveness and that she is out with him only as a favor to a friend. Some may find this brutal honesty refreshing, but others could see the benefits of white lies or chosen moments of silence.

Mark works as a screenwriter for a film studio. However, fiction does not exist because there is no lying, so all films are dull historical lectures. Mark is soon fired and he goes to the bank to pay his rent. The computers are down when the teller asks him how much is in his account. Mark says he has \$800, the first lie ever told. When the computer reboots and shows that he has only \$300, the teller presumes it must be a computer error. This lie to pay his rent leads to more lies: Mark gets a friend out of a driving-under-the influence (DUI) charge, wins a casino jackpot, and tells a woman that the world will end unless they have sex. He also pens the first fiction, adding aliens into his historical screenplay. The surprising film is a wild success and no one has reason to doubt Mark's veracity. Now rich and famous from his lying, Mark asks Anna out on another date. While happy for his success, she still expresses concern that his poor genes will give them undesirable "little fat kids with snub noses."

Mark's mother suffers a heart attack. She is petrified of death, so to console her Mark tells her that, after she dies, she will be with all the people she loves, feel no pain, and have her own mansion. The staff overhears Mark's depiction of a heaven and people soon flock to him to learn more about the afterlife. To appease everyone, Mark, serving as a variant of the biblical Moses,

creates a biblical story of a "Man in the Sky" God figure and presents 10 rules to live by. Still, while Mark single-handedly creates religion through his lies, he refuses to deceive Anna into marrying him instead of his rival Brad (Rob Lowe), and Anna almost marries Brad but does not.

### Commercial and Critical Reception

*The Invention of Lying* cost \$18.5 million to produce and made \$18.45 million in the United States. However, film studios split revenues with theater chains, and marketing and promotion budgets add additional costs to each film's bottom line. *The Invention of Lying* made an additional \$14 million on international screens, with \$9.8 million coming from Gervais's native country, the United Kingdom. The film ranked 113th in earnings of all 2009 films, three spots above Oscar winner *The Hurt Locker*. In January 2010, it debuted as the third-most popular DVD release.

While Gervais was nominated for the Peter Sellers Award for Comedy at the *Evening Standard's* British Film Awards, the film received no other critical accolades or nominations. Critics were mixed, as some enjoyed the comedy and the film's clever and unique premise, while others found the film filled with more romantic comedy clichés than truly comedic moments.

### Research Application

Lying is a part of everyday life. Research finds that both college students and community members admit to lying on a regular basis, and they do not consider their lies to be serious or worry about being caught. Though research finds that social interactions with lies are less pleasant, the film characters' blunt honesty toward Mark certainly could hurt positive social interaction as well. However, it is important to differentiate truth from manners, as a situation without lying does not necessitate harsh, offensive truths.

The film raises the question of whether all lies are necessarily bad, as some might be a normal part of the social world. People often consider white lies to be innocuous, whether they are altruistic white lies (to help others) or Pareto white lies (to help both others and the liar). However, recent research suggests that telling a white lie might lead to cognitive dissonance and negative affect. Additionally, clinical oncology research found

that concealing information from terminally ill patients was generally less stressful for clinicians than sharing the truth about the diagnosis. These research findings are seen in the film, as Mark lies about heaven to reduce the stress of the situation and help his mother on her deathbed. Then, as people believe the lie, Mark creates more elaborate religion-tinged lies to help those who believed the first lie.

the tendency to judge other people's statements as deceptive and reduce confidence in the accuracy of judgments. Thus, trained or experienced investigators appear to be biased to see deception in the communications of others.

### Possible Reasons for Bias

The effects of training may be a consequence of training programs focusing on the detection of deception (not truthfulness). Jaume Masip and colleagues found that significantly more deception judgments were made after being trained to detect deception than before the training. Opposite results were found for truth-detection training, which increased truth judgments. The authors argued that after the training, trainees search actively for the learned cues, which may be displayed by both liars and truth-tellers (though with different frequency), and as soon as they believe they have noticed any of these cues they make their judgment. The perceived frequency of the cues predicted participants' judgments.

Concerning experience, the same researchers found that veteran police officers scored higher on a scale measuring generalized communicative suspicion (GCS), which is a predisposition toward believing that other people's messages are deceptive, than novice officers and nonofficers. Police officers' daily involvement in contexts in which distrust is salient might enhance their generalized suspicion. However, a follow-up study revealed that GCS scores were unrelated to veracity judgments and that novice officers made as many deception judgments as experienced officers. Anyhow, officers' interest in solving cases might bias them to search for deception rather than truthfulness cues.

### Guilt-Presumptive Questions

A danger of the investigator bias effect is that once the belief is formed that a particular suspect is lying, the investigator may ask only guilt-presumptive questions, displaying confirmation bias, a phenomenon that consists of selectively searching for information in support of one's beliefs or expectations, dismissing contradictory evidence, and interpreting ambiguous evidence as consistent with one's beliefs or expectations. This may in turn result in a self-fulfilling-prophecy effect if the guilt-presumptive interrogation generates

---

## Investigator Bias

The concept of investigator bias was coined by Christian Meissner and Saul Kassin, who found in a meta-analysis that neither deception-detection training nor experience in lie-detection-related jobs (for example, law enforcement) increase accuracy (that is, correct classification) in identifying truths and lies. Instead, training and experience increase

in the suspect objectively suspicious reactions—which are a consequence of the type of questioning rather than of the suspect's actual guilt or innocence. A number of studies have shown that confirmation bias and self-fulfilling-prophecy effects do occur in interrogation situations.

Saul Kassin and collaborators found that relative to interrogators in an innocent-expectation condition (induced to believe that the suspect was probably innocent), interrogators in a guilty-expectation condition (GEC) chose more guilt-presumptive questions when preparing the interrogation, used more different interrogation techniques at the onset of the interrogation, and tended more strongly to judge the interviewee as guilty. Observers blind to the experimental manipulations listened to the audiotaped interviews and rated interrogators in the GEC as more guilt-biased, exerting more pressure on the suspect, and trying harder to obtain a confession (in particular when interviewing innocent suspects) than interrogators in the other condition. These strategies resulted in a self-fulfilling prophecy effect, as the observers perceived suspects questioned by interviewers in the GEC as more defensive and marginally more guilty than those questioned by interviewers in the innocent-expectation condition.

Similar results were reported by Carole Hill and her colleagues, who additionally found that guilty and innocent suspects interviewed with guilt-presumptive questions felt stronger pressure to confess (although actual confessions did not depend on the type of questioning but on actual guilt), and that participants who listened to only the suspects' responses rated suspects interviewed with guilt-presumptive questions as more defensive, nervous, and guilty than those interviewed with neutral questions. Among innocent suspects, the denials of those interviewed with guilt-presumptive questions were judged as less plausible than the denials of those interviewed with neutral questions.

An early judgment of deception or guilt influences not only the interrogator's behavior during the interview, but also the memory and interpretation of the facts, as well as the kind of additional evidence to be sought. Barbara O'Brien asked participants to read a police file with information about a case. The first half of the file contained

circumstantial evidence against a designated suspect, while the second half contained both more evidence against this suspect and new evidence that questioned his guilt. Unlike participants in the no-hypothesis condition, participants in the hypothesis condition had to name their primary suspect after reading the first half of the file (virtually all named the designated suspect). Later on, in comparison with the no-hypothesis condition participants, those in the hypothesis condition remembered facts as more consistent with the designated suspect's guilt, interpreted ambiguous or inconsistent information more in line with the designated suspect's guilt, requested more reports and advocated more lines of investigation focused on that suspect, and ultimately were marginally more likely to judge the designated suspect as the culprit.

In sum, trained or professional investigators are not particularly good truth- and lie-detectors; instead, they are biased toward making deception judgments and tend to judge suspects as guilty. This yields confirmation-bias and self-fulfilling-prophecy effects that ultimately reaffirm the investigators' belief in the suspect's guilt. What remedies can be taken?

### Alleviating Bias

It has been suggested that training programs oriented to detect the truth in addition to deception might compensate the biasing influence of lie-detection-oriented programs. However, it is uncertain whether this might work with professional investigators, who must detect liars (guilty individuals) rather than truth-tellers. Another strategy was suggested by J. Pete Blair, who found that providing information at the end of the training can create an undesirable lie bias; and if one is not sure about someone's truthfulness, it is better to indicate that this person is truthful, which counteracted the lie-biasing effect of training.

Finally, Barbara O'Brien tested two strategies to neutralize confirmation bias in criminal investigations in a study similar to the one described above but with two additional groups. The counterhypothesis group had to list reasons why the preferred suspect might be innocent, whereas the list-three group had to list three suspects and evidence for and against each of them. The

counterhypothesis manipulation was successful in neutralizing the confirmation bias, but the list-three manipulation was not successful—perhaps because of the relative ease with which participants generated a case against the designated suspect. Thus, searching for reasons why the primary suspect might be innocent can counteract the confirmation bias.

## Investment Fraud

Investment fraud involves theft by deception. Its victims are unwary individuals who purchase or sell securities or commodities with the expectation of a profit or return in the form of interest, dividends, or income. Investment fraud comes in many varieties. It can occur when scammers lie or fail to disclose information in order to manipulate the investment market, causing victims to incur losses while the fraudster makes profits. Or it can be accomplished in more direct ways, such as a Ponzi scheme, in which an investment broker takes an individual's money under the guise of investing it but makes no such transaction for the individual. It can also take place when corporation officers or investment bankers overstate their profits and assets, or understate losses and liabilities, in order to deceive shareholders into believing an entity appears to be healthier than it actually is.

Protections in place to safeguard investors from fraud include federal and state regulatory agencies and federal laws such as the Securities Act of 1933, Securities and Exchange Act of 1934, Investment Advisers Act of 1940, Insider Trading and Securities Fraud Investment Act of 1988, Sarbanes-Oxley Act of 2002, and the Dodd-Frank Wall Street Reform and Protection Act of 2010. The Securities and Exchange Commission (SEC) conducts administrative hearings and can file lawsuits resulting in injunctions (to stop a practice), fines, and disgorgements (forfeitures of profits). The SEC can also refer cases to the U.S. Department of Justice for the filing of criminal charges, resulting in fines, restitution, probation, and imprisonment. The burden of proof to obtain a conviction is greater in criminal cases, in which guilt must be proved beyond a reasonable doubt, than in civil actions, in which only a preponderance of evidence is required to obtain a finding.

### Illegal Market Manipulation

Since the very act of investing carries with it a risk of losing one's money, it is often difficult to detect if a fraudster was involved behind the scene of an investor's loss. Illegal market manipulation illustrates this point. It includes such unscrupulous practices as operating out of a boiler room, churning, front running, pump and dump, poop

and scoop, short and distort, and insider trading. A boiler room is a large room crammed full of high-pressure telemarketers making cold calls to dupe unsuspecting customers into buying often troubled microcap (for example, penny) stocks. If the potential customer could see the caller's surroundings, no deal would take place. But boiler rooms are charades and are often staffed by individuals pretending to be licensed brokers.

Churning is the practice of a broker excessively trading a client's stock for the primary purpose of earning commissions. Front running is the practice whereby a stock analyst buys shares in a company knowing that a brokerage is going to be strongly recommending the stock to others, or a broker buys shares in a company knowing that his client will be buying a large order of the same stock. This drives the price of the stock up, costing clients more, but allows the broker to make a profit when he sells the stock after its price has risen.

Pump and dump involves spreading lies to artificially inflate (pump) the price of a stock. Schemers circulate false or misleading information, producing hype and a rise in the stock's price as a large number of people buy it. At this point, the fraudster sells (dumps) his own stock at a profit, while the recent investors lose because the price falls back to where it was before the pump. Poop and scoop may be seen as the opposite of pump and dump. In this practice, a few investors spread fabricated harmful information or rumors about a company or its stock, so that they can then buy the stock (scoop it up) at a bargain price when it falls (poops) as a consequence of the smear.

Short and distort is a scheme that begins with a perfectly allowable strategy (known as a short sale or selling short), involving the sale of a security that is not owned by the seller, but is rented or borrowed for the purpose of selling it to someone else. For instance, a broker may lend a security to an investor from his own inventory. At some point, the investor has to "cover" by purchasing the same type of security to return what he had borrowed. If the price drops in the interim, the investor profits. It becomes a short and distort scheme when an individual engages in illegal manipulation of the market, such as spreading untruthful information (distorting) to cause the stock's price to fall.

### Insider Trading

Insider trading is a type of fraud committed by nondisclosure. If a seller or buyer of a publicly traded stock has acquired privileged information about that corporation, upon which he bases his trade, and if he fails to disclose to his counterparty that he has such information, he has defrauded his counterparty. Well-publicized cases centering on insider trading are those of Raj Rajaratnam, Sam Waksal and Martha Stewart, and Eugene Plotkin and David Pajcin.

Having founded and managed Galleon Group (one of the world's largest hedge funds), billionaire Rajaratnam is considered the most influential figure thus far to have been found guilty of insider trading. His 2011 conviction resulted in the longest sentence given, to date, for this type of offense. Additionally, he was ordered to pay close to \$160 million combined in criminal fines, disgorgement, and civil damages.

Sam Waksal, founder and former chief executive officer (CEO) of Imclone (a biotech company), and his friend, television celebrity Martha Stewart, were embroiled in allegations of insider trading. In 2004, Stewart was found guilty of obstruction of justice and lying to the government. Waksal had pled guilty to securities fraud the preceding year and received a seven-year prison sentence. He admittedly had tried to sell his Imclone shares after learning (before the public announcement) that the Food and Drug Administration was not going to approve the company's new cancer drug. He also transferred a large number of shares to his daughter and to his father, advising them to sell these shares. Waksal denied having told Stewart to sell her shares. She maintained she had a standing stop-loss order with her broker to sell the shares if the share price fell below \$60. After serving his prison sentence, Waksal publicly stated his regret for having involved his family members in his deception and said that he learned from the experience that one should never lie to SEC investigators.

A more complicated and widely orchestrated insider trading case was that involving bond researchers Eugene Plotkin and David Pajcin. They devised a plan that included obtaining advance copies of the "Inside Wall Street" column in *Business Week*, as well as using confidential information from coconspirator Stanislov Shpigelman,

*The President's Economic Recovery Advisory Board (from left, Vice President Joe Biden, President Barack Obama, Paul Volcker, and Mark Gallogly) meets in the Roosevelt Room of the White House, April 16, 2010. Before the meeting, Obama remarked on Wall Street reform by assuring that he would veto any legislation that did not bring the derivatives market under control. The Dodd-Frank Wall Street Reform and Protection Act was signed into law three months later on July 21, 2010.*

who worked in the mergers and acquisitions department of Merrill Lynch, a global investment management company. Plotkin and Pajcin placed orders for themselves and for others before recommendations were published in *Business Week* and while Merrill Lynch was working on deals that had not been publicly disclosed.

The SEC's surveillance department takes note of sudden surges in the trading of a company's stock, especially within days of a merger between companies. That agency became suspicious when a 63-year-old retired seamstress in Croatia (Pajcin's aunt) came into a \$2 million windfall of earnings from her Reebok stock that she had bought just before Adidas acquired Reebok. She had utilized a call option (a contract allowing one to lock into a buying price before the contract's expiration date), and during a two-day period had made 17 times the amount of her initial call option. From the Reebok trading, as well as trading on advance information of a Gillette takeover by Proctor & Gamble, Plotkin and Pajcin's insider trading ring netted \$6.7 million. In addition to receiving fines and prison sentences in 2008, the two were ordered to forfeit their profits.

### **Ponzi Schemes**

Ponzi schemes derive their name from Charles Ponzi, who in 1920 in Boston was discovered to

have swindled more than 10,000 investors out of \$20 million within an eight-month period. He lured victims into an international postage stamp business opportunity with the promise of a 50 percent return within 90 days. He paid investors what appeared to be returns by using the newer investors' money, after keeping most of the money for himself. Thereafter, any scheme that paid earlier investors with money from recent investors became known as a Ponzi scheme.

This type of confidence game depends upon so-called songbirds—investors receiving returns who sing the praises of the investment opportunity to others, who then want to take part in it. When individuals realize that they are the victims of a Ponzi scheme, in addition to experiencing their own financial losses, they have to deal with the realization that they had encouraged others (for example, friends and relatives) to buy into the investment opportunity in which they had mistakenly put their trust. Ponzi schemes usually collapse when either authorities discover they are fake or when investors in large numbers need to withdraw their money (for example, during an economic downturn).

In Ponzi's case, someone became suspicious and figured out that there were only 27,000 International Reply Coupons in worldwide circulation, and Ponzi would have needed 160 million of

such postal coupons to succeed with his promised profit to his investors.

A Ponzi scheme receiving wide notoriety was that of Bernard Madoff, who was sentenced in 2009 to 150 years in prison. He had collected \$36 billion from 13,000 account holders, while paying out \$18 billion in returns. When one includes the amounts investors falsely were led to believe they had earned, Madoff's fraudulent activities totaled nearly \$65 billion. When the 2008 financial crisis occurred and a large number of investors needed their money, the scheme fell apart. It was at that time that Madoff's confession to his two sons took place, and they, in turn, notified authorities.

Although Madoff admitted to having run the scheme since the early 1990s, it may have been going on longer than that. He had gone undetected for so many years because he had a very good reputation in the financial community and had served as chairman of the National Association of Securities Dealers Automated Quotations (NASDAQ). Harry Markopolos, an analyst, had tried unsuccessfully on several occasions to convince the SEC that Madoff's figures were impossible to achieve.

Other lesser-known Ponzi schemes were exposed around the same time as Madoff's, but they were overshadowed by the media coverage surrounding Madoff. Approximately 190 Ponzi schemes reportedly collapsed between 2008 and 2009, when the economy was suffering. Five days before the public learned about Madoff, Marc Dreier was arrested for several crimes, including a \$380 million Ponzi scheme. The scheme involved selling bogus promissory notes to hedge funds and providing clients with fictitious financial statements of earnings. Dreier, who ran his own lucrative Manhattan law firm, led a lavish lifestyle. But as he later explained during an interview, he felt he had not achieved the level of success that he had hoped to reach. He received a 20-year prison sentence in 2009.

Nicholas Cosmo's \$400 million Ponzi scheme was also uncovered in 2009. Cosmo led 1,500 investors into believing they could earn a 50 percent annual return by backing commercial bridge loans (short-term interim loans pending longer-term financing). In actuality, only \$30 million of the money taken from investors was used for such loans. Unlike Madoff and Dreier, who catered to

wealthy clients, Cosmo tended to have working-class and middle-class clients, who lost their entire savings as a consequence of their involvement with him. He was sentenced to 25 years in prison.

### Corporate Fraud

Corporate fraud (for example, misleading shareholders) is exemplified by the cases of Enron and WorldCom. In 2001, it was discovered that Enron, an energy trading corporation, had been overstating assets through several accounting tricks, including the creation of partnerships that hid its debt. The sham partnerships were allowing Enron to show profits while it was losing money each year and was \$30 billion in debt. Irregularities in bookkeeping were ignored by accountants, who served both as auditors and paid consultants for the company. Additionally, Enron was underhandedly persuading analysts to recommend Enron stock to potential investors as a strong buy. Enron's overvalued stock gave the company an illusion of success.

After the fraud was exposed, the company's stock, which had once sold for almost \$90 per share, fell to 40 cents, and Enron, the country's seventh-largest corporation at the time, went bankrupt. Enron's investors lost over \$70 billion. The losses were not limited to outside investors, as Enron employees and retirees lost their pensions and 401(k) plans. Former CEO Jeff Skilling received a 24-year prison sentence, while former Chief Financial Officer Andrew Fastow received a six-year sentence after pleading guilty and serving as the prosecution's chief witness against other company executives. Kenneth Lay, Enron's founder and chairman of the board, died before he could be sentenced.

The year after Enron's bankruptcy, WorldCom, a telecommunications corporation, experienced its own accounting scandal and bankruptcy. Instead of listing \$3.8 billion as expenses, the company listed that amount as long-term investments. CEO Bernie Ebbers had resigned amid questions about receiving \$366 million in personal loans from the company. He received a 25-year prison sentence for securities fraud. The company's stock that had sold for \$64 per share in 1999 had plummeted to 21 cents at the time of the bankruptcy.

As a consequence of the fraud committed at Enron, WorldCom, and other corporations

during the white-collar crime wave that occurred between 2000 and 2002, Congress passed the Sarbanes-Oxley Act. In an effort to safeguard the interests of investors who buy stocks in publicly traded companies, the act includes requirements that CEOs certify the accuracy of their company's books, analysts be independent of the companies they evaluate, personal loans from companies to their top executives be banned, and nonaudit functions of auditors for public companies be restricted to avoid conflicts of interest. Additionally, when selling their shares of the company's stock, top executives are required to take reasonable steps to disclose such activity to shareholders. Had such a rule been in place during the months preceding the fall of Enron, its shareholders could have had some warning when Enron's top decision makers were unloading their stocks.

### Mortgage-Backed Securities Fiasco

Investment banks have also been known to misrepresent their worth. This appears to be the case in the mortgage-backed securities fiasco of 2006–08. As of the beginning of 2013, there had been no criminal prosecutions alleging fraud by the issuers of mortgage-backed securities, because intent is difficult to establish. Problems began when lending institutions started granting subprime mortgage loans to very risky borrowers, then bundled those loans as derivatives, and sold trillions of dollars worth of these as mortgage-backed securities, to mostly institutional investors.

In defense of their subprime loans, lenders contended that there was reason to believe that even the riskiest borrower (with a limited income, large debt, or poor credit history) had the ability to pay back the loan by selling his home at a profit after it appreciated in value. But when the housing bubble burst because of the unusually large number of foreclosures and homes for sale, the plan fell apart. Investors lost their money in troubled mortgage-backed securities.

By late 2012, civil suits by the SEC and New York's attorney general were targeting J.P. Morgan, the country's largest bank, which was being held accountable for mortgage-backed securities that Bear Stearns, a major investment services firm, had engaged in prior to being acquired by J.P. Morgan. Additionally, in early 2013, the government brought a civil suit against the credit

rating agency Standard & Poor's for misleading investors into believing that mortgage-backed securities were safe.

### Conclusion

While investing is always a risk, it becomes riskier when others covertly work against the investor by engaging in lying, pretense, nondisclosure/omissions, misleading statements, or any other related form of dishonesty or guile that deprives the investor of fairness or honest services. Investment fraud may be committed by private investors, brokers, financial advisers, corporations, financial institutions, and other institutions and individuals. In the long run, the victims of investment fraud include the entire society whose members lose trust in fiduciaries and the overseers of financial markets. Widespread loss of confidence in the investment market can have serious consequences for the entire economy.

## Iran-Contra Affair

Iran-Contra was a political scandal in the mid-1980s during the presidency of Ronald Reagan. From the beginning of his first term in office,

President Reagan and his administration had been supporting and funding rebel contras (counter-revolutionaries) in their fight against the Sandinistas for political power in Nicaragua. Partisan politics led Congress to pass the Boland Amendments, sponsored by Representative Edward Patrick Boland, a Democrat from Massachusetts. The amendments aimed to control American contributions to the contras. Congress also set a cap of \$24 million for the contras during 1983, and the Reagan administration was disappointed in the amount of money appropriated.

### **Alternative Funding Methods**

Robert McFarlane, Reagan's national security advisor, and William Casey, director of the Central Intelligence Agency (CIA), agreed that a way to fund the contras would be to find third-party countries that would be willing to donate to this group. Saudi Arabia agreed to give \$1 million per month, so McFarlane and Casey set up a private bank account to move the money from Saudi Arabia to the contras. When Congress decided against giving any money to the contras in 1984, Reagan entrusted McFarlane and Oliver North, deputy director of political-military affairs, to keep the contras' mission alive. After this cut in funding, the National Security Council (NSC) took over the contras case from the CIA.

North devised many ways to fund the contras, including private funding, foreign aid as a leverage for other countries to support the contras (specifically Honduras), and continuing to find third-party countries willing to donate. In 1985, Congress granted \$27 million in humanitarian aid to the contras with the stipulation that the State Department administer the aid. Reagan quickly created the Nicaraguan Humanitarian Aid Office (NHAO) in the State Department and demanded the funds be sent to Nicaragua immediately. North used NHAO to plant people in Nicaragua. At this time, Congress inquired as to the working relationship between the NSC and the contras, but the representatives lied on multiple occasions in order to cover up their secret operation.

Iran became a party to the scheme in the summer of 1985. In order to secure the release of American hostages held in Lebanon, Israel sent U.S.-supplied weapons to Iran in return for Iran's help in releasing the hostages. Along with the

hostage situation, the United States was worried about Soviet influence in Iran. Over the next year, until November 1986, the United States worked with Mancher Ghorbanifar, an Iranian who said he could obtain the release of the hostages. The United States sent thousands of Hawk missiles and tube-launched, optically tracked, wire command-link (TOW) missiles in order to gain release of the hostages.

This is precisely when North discovered how lucrative the selling of arms to Iran could be. North was able to purchase TOWs from the Department of Defense for \$3,700. In turn, he sold these TOWs to Iran, through Israel, for \$10,000 each, never disclosing the price difference. The proceeds from this price difference were then sent to aid the Nicaraguan contras. This diversion continued until November 1986, when the secret operations were leaked and what is now known as Iran-Contra became public.

### **Deception in Politics and Security Policy**

Deception in politics and security policy is an ongoing theme. President Reagan and his NSC were not the first government officials to use high levels of lying and deception in their work. For example, the Case-Zablocki Act was enacted in 1972 to stop the executive branch from entering into agreements with foreign countries without notifying Congress. This act required the president to notify Congress of any international agreements the executive branch made in which the United States was a party.

For similar reasons, the War Powers Resolution of 1973 was enacted in order to reign in presidential military decisions that were made without the consent of Congress. This resolution was created after consecutive presidents bypassed congressional approval during the Vietnam War, and President Richard Nixon secretly authorized bombings in Cambodia and Laos. After these laws were adopted, presidents started using tactics such as "nonagreement" agreements and treaty reinterpretations to circumvent these restrictions. All of these agreements could be seen as a way for the executive branch to expand its power by deceiving Congress.

Similar types of deception are evident in the Iran-Contra scandal. The entire Iran-Contra situation was hidden under a blanket of deception.

On multiple occasions Congress inquired as to the activities of President Reagan and his role in helping the Nicaraguan contras. Different people involved in the situation repeatedly told Congress that they were not doing anything illegal. One of Reagan's national security advisors, John Poindexter, even went so far as to destroy a Presidential Finding that Reagan had signed, which said he knew about a Hawk missile shipment in November 1985 but was not aware it was an arms-for-hostages situation. Poindexter destroyed this finding because he believed that if the document was found by people not involved in Iran-Contra, it would be an embarrassment to the president. Moreover, once the scandal was leaked to the public, North destroyed multiple documents in order to hide his large role in the situation.

Lying and deception also was a factor in the prosecution of the people involved in Iran-Contra. North was tried on 11 charges, including aiding and abetting and obstruction of congressional inquiries in November 1986, destroying and falsifying official NSC documents, and receiving illegal gratuities. Throughout his entire trial, North claimed that he believed he had been acting under full support and approval of his superiors, including President Reagan. This would indicate that he had been deceived if he actually did not have presidential approval, or that he was deceiving members of Congress and the American public if he was working without presidential permission.

While the NSC and those involved used deception and lying as a large part of their cover-up of Iran-Contra, North was using these same techniques in order to receive a not guilty verdict in his prosecution. President Reagan escaped prosecution by saying he did not know the extent to which this situation had evolved. In a *New York Times* article published on November 26, 1986, Reagan said he had not been in charge of his administration's policy toward Iran and pointed the blame at North and Poindexter. It is still unclear to this day how much Reagan knew.

### Conclusion

Lying and deception have become a more public part of politics within the past few decades. Presidents have lied and deceived to bypass Congress in multiple arenas, including military affairs, foreign

policy, and fiscal decision making. In the Iran-Contra situation, lying and deception aided in the short-term expansion of the power of the executive branch and some of the agencies within it.

## Iraq War

The United States was engaged in a war in Iraq from March 20, 2003, until December 18, 2011. The most notable incidents of lying and deception during the war involved (1) the United States' violation of the Geneva Conventions and the country's subsequent denial of its direct connection to prisoner abuse at the Guantanamo Bay Naval Base, the Abu Ghraib prisons, and other military sites; and (2) the United States' mischaracterization of Iraq as a country that possessed weapons of mass destruction (WMD).

Records from international organizations as well as several U.S. government agencies confirm the U.S. government had been cautioned of

its violation of the Geneva Conventions as early as January 2002. The George W. Bush administration disregarded these allegations until 2004, when photographs of prisoners at Abu Ghraib, Iraq, leaked and the scandal went viral.

While there exist thousands of photographs and videos of the abuse in Abu Ghraib, only a handful of pictures circulated in the media. When these photographs became public, the U.S. government negated any awareness of prisoner maltreatment, exculpated senior officials who knew and took part in the organization of these acts, and attributed the incidents of abuse to a group of low-ranking soldiers stationed at Abu Ghraib.

Regarding the distortion of Iraq as a country armed with WMD, the U.S. and British governments accepted allegations provided by foreign intelligence that incriminated Iraq as possessing WMDs. These documents, later discovered to be false, stressed that since the Gulf War, Saddam Hussein had continued to develop WMD with the intentions to damage neighboring regions and disrupt the world's stability. By the time President Bush made his State of the Union address in 2003, an array of these claims had already been exposed as faulty, although the president's speech perpetuated the information as credible. Later in 2003, the lack of evidence against Iraq directed the White House to correct the widespread misconceptions by suggesting the real concern regarded Iraq's program for developing WMD and not the weapons themselves. Investigators from the United States and the United Kingdom (UK) never found weapons of mass destruction in Iraq.

### **Defiance of Geneva Conventions**

An important government source that demystifies pervasive narratives regarding the Abu Ghraib scandals is the Levin-McCain report, released on December 11, 2008. This report summarizes investigations of various government "cover ups" and lists a timeline for the incidents of abuse. The Levin-McCain report explains how the incidents of prisoner maltreatment were not the actions of "a few bad apples," as mainstream media had depicted it, but rather a systematic practice of abuse passed from the top down.

This and other documents mark February 7, 2002, as an important date for understanding

the events that followed. On this day, President Bush announced that members of the Taliban and Al Qaeda were not protected by the principles of the Third Geneva Convention, which affords war detainees prisoner of war (POW) status. This interpretation of the law prohibited Al Qaeda and Taliban affiliates from receiving the humane treatment mandated in Common Article 3 of the Geneva Conventions and enabled these members to be treated as "unlawful combatants" who were not entitled to the protection of international law. The Bush administration deemed the Geneva Conventions inapplicable in this war because Iraq was a "failed state." This reinterpretation of international law produced a new military policy that severely affected the treatment of Iraqi detainees under U.S. custody.

In December 2001, before the president adopted his new policy regarding the Geneva Conventions, the U.S. Department of Defense (DoD) General Counsel's Office requested information from the Joint Personnel Recovery Agency (JPRA) regarding detainee "exploitation." The JPRA is a government division that supervises military training to build resistance in soldiers in the event soldiers become prisoners. This agency bases training on illegal practices that violate the Geneva Conventions. The training includes building physical and psychological endurance against stress; being stripped of one's clothes; and being exposed to sleep deprivation, humiliation, waterboarding, and physical pain. In July 2002, the JPRA's deputy general counsel for intelligence confirmed the purpose of this request was to "reverse engineer" the endurance training.

Although most of the records between JPRA and the DoD remain classified, unclassified material brings attention to a number of senior officials who took part in JPRA meetings, debriefings, and correspondence regarding new interrogation techniques. Some of these senior officials include DoD General Counsel William Haynes II, JPRA Chief of Staff Lieutenant Colonel Daniel Baumgartner, JPRA senior psychologist Bruce Jessen, Deputy General Counsel for Intelligence Richard Shiffrin, Attorney General John Ashcroft, Assistant Attorney General Jay Bybee, Secretary of State Condoleezza Rice, National Security Council legal advisor John Bellinger, and Secretary of Defense Donald Rumsfeld.

### Interrogation and Torture

In August 2002, Bybee wrote to White House Counsel Alberto Gonzales, describing options that attempted to redefine the meaning of torture. The first of the options explains that for an act to be considered torture it must include physical pain amounting to the equivalent in intensity of organ failure as well as psychological harm that lasts for months or even years. The second of the options remains classified. However, records relating to this document show that waterboarding was among the techniques listed and approved to gather intelligence in Iraq.

Having redefined the applicability of the Geneva Conventions and what constitutes torture, officials at the Guantanamo Naval Base requested that Rumsfeld give them permission to use stronger methods of interrogation. Rumsfeld approved 16 of the techniques, including the use of hooding, stress positions, stripping, and deprivation of light as methods to aid the interrogation process. Rumsfeld approved the techniques without further instructions as to how they should be overseen.

In addition to approving these interrogation techniques, Rumsfeld and Haynes created a working group to work out the legal details of the new interrogation tactics. The working group was finalized on March 2003, months after global humane organizations such as Human Right Watch, Amnesty International, and the Red Cross had raised concerns about the way American troops were treating detainees in custody. The interrogation techniques resemble reversed JPRA endurance training.

Memos of these and other interrogation techniques approved by Rumsfeld traveled from Guantanamo to Iraq. Although the U.S. government abandoned authority over the more aggressive interrogation techniques in January 2003, Rumsfeld's initial consent continued to influence the tactics for gathering intelligence.

Interrogation techniques that violated Geneva Conventions were widespread in many sites holding war detainees. Common practices included yelling at detainees, environmental manipulation, sleep deprivation, stripping detainees of their clothes, and 20-hour-long interrogations. These techniques eventually became standard operating procedures issued for all U.S. forces in Iraq. Abusive interrogation practices were not specific

to Guantanamo and Abu Ghraib. Camp Bucca, Camp Cropper, and Bagram Air Base, rank among the sites known for violent interrogation tactics.

### Pressure for Humane Treatment

In October 2003, increasing concern from humanitarian organizations began to induce a growing pressure regarding the humane treatment of detainees. In attempts to address these issues, U.S. forces eliminated previously authorized techniques; however, the new policies were confusing and ambiguous to the soldiers.

On January 31, 2004, the White House appointed Commanding General Antonio Taguba to carry out a formal investigation regarding allegations of abuse in the Abu Ghraib prisons. The Taguba Report showed that between October and December 2003, incidents of criminal abuse were inflicted on several detainees at Abu Ghraib. The report noted a long list of abuses, including physical infliction of pain, videotaping and photographing naked detainees, forcibly arranging detainees in sexually explicit positions, stripping detainees of their clothing and keeping them naked for several days at a time, forcing groups of male detainees to masturbate while being photographed, placing a dog chain around a naked detainee's neck, and using working dogs without muzzles to intimidate detainees. Further, the Taguba Report brought attention to problems involving the chain of command at Abu Ghraib.

After the Abu Ghraib scandals became public, President Bush offered an apology to the Arab community for the "humiliation" of Iraqi prisoners. He referred to the practices of torture as "abhorrent" but kept Rumsfeld as part of his cabinet, noting that Rumsfeld was a good secretary of defense. The Bush administration blamed the acts of abuse on a few so-called sadistic soldiers. These soldiers were tried in military courts martial, convicted of the abuses, and received dishonorable discharges after serving time in prison; some of their superiors were demoted. Senior officials working for specialized government agencies and the White House did not face severe consequences.

### Weapons of Mass Destruction

As early as September 2002, CIA director George Tenet reassured President Bush that Saddam

Hussein did not have weapons of mass destruction. Almost a year before the debriefing, the U.S. government's leading nuclear experts maintained that it was extremely unlikely that Hussein was importing aluminum tubes to Iraq for developing nuclear centrifuges. The White House dismissed these claims and instead noted other allegations of WMD possession by Iraq as reasons for engaging war with the country.

The U.S. stance regarding Iraq's possession of WMD was largely supported by the UK government and Prime Minister Tony Blair, who released an evaluation of Iraq's alleged involvement with nuclear weapons since the Gulf War. "Iraq's Weapons of Mass Destruction: The Assessment of the British Government," also known as the "September Dossier," details a long list of claims about Iraq in relation to WMD. The document was released September 24, 2002. Among the most noted claims, the report accused Iraq of continuing to produce nuclear agents after the Gulf War, having military tactics for using WMD

against its own Shia population, having weapons that were deployable within 45 minutes of an order to use them, developing mobile laboratories, illegally possessing missiles that were capable of carrying chemical and biological warheads, and building a new test stand for missiles that could reach the United Kingdom, the Sovereign Base in Cyprus, NATO affiliates in Greece and Turkey, and the people of Israel. Finally, based on information provided to the UK and the United States by the Italian military intelligence service known as Sismi, the accusations blamed Iraq for seeking to obtain significant quantities of uranium from Niger and accounted illegal earnings of \$3 billion to fund WMD in 2001.

On February 5, 2003, Secretary of State Colin Powell presented the case to the United Nations Security Council, bringing attention to these facts as well as the discovery of two trucks in Mosul, Iraq, which Powell used as proof that Iraq had mobile WMD. Later investigations revealed that the trucks had zero traces of biological agents and

*Two R-400A bombs, photographed by United Nations Special Commission inspectors near the Al Walid Airbase, Iraq, in late 1991, bear markings indicating they were to be filled with botulinum toxin. Other bombs had markings consistent with binary chemical agent fill. This evidence contradicted Iraq's declarations that it did not deploy biological weapons to operational airbases and that it destroyed them in July 1991; this claim was subsequently retracted in the face of overwhelming evidence to the contrary. Iraq's long history of deception lent credence to Italian intelligence reports, later found to be false, claiming Iraq possessed nuclear weapons of mass destruction.*

that the documents warning of Nigerian yellowcake were forged by Italian spy and Sisimi director Rocco Martino. When questioned about the authenticity of the facts, Powell replied that the reports were accepted in “good faith.” The U.S. and British governments never addressed how their intelligence agents did not recognize that the evidence was fake.

## Irving, Clifford

In the early 1970s, investigative journalist Clifford Michael Irving perpetrated one of the most famous hoaxes in the history of publishing when he delivered a manuscript to publisher McGraw-Hill that he claimed was based upon interviews he had conducted with reclusive American billionaire Howard Hughes, whom he had never met. Irving reported that he interviewed the notoriously private billionaire at retreats in the Bahamas, Florida, and Mexico. Originally, the book Irving pitched was conceived as an authorized

biography. However, the transcripts of the fully developed fake interviews he purportedly conducted with Hughes during the process of preparing the biography proved to be such compelling reading that it was decided they should be edited and released in the form of an autobiography. This alleged autobiography was scheduled to be published in 1972.

### Howard Hughes’s Fictional Autobiography

McGraw-Hill’s commercial interest in publishing Hughes’s autobiography was prompted by continued public fascination with Hughes because of his enormous wealth, fabled exploits, and unconventional lifestyle. In his prime, Hughes had earned a large fortune for his pioneering work in both films and aviation, and he invested his money wisely, resulting in Hughes becoming one of the world’s wealthiest people. The same work that made him rich also made him famous, as did his reputation as a womanizer who had dated such high-profile Hollywood stars as Bette Davis, Ava Gardner, Olivia de Havilland, Katharine Hepburn, and Ginger Rogers.

After decades of high profile celebrity Hughes then retired completely from public view, living in protected seclusion in a series of upscale hotel sanctuaries in Las Vegas, Beverly Hills, Boston, the Bahamas, and elsewhere. Hughes’s prolonged absence from public view after years of being a famous celebrity only served to increase interest in him, fueling rumors about his mental and physical health, his living conditions, and other details of his private life.

In perpetrating his hoax, Irving duped his publisher into believing that Hughes had written him a series of letters. These were forgeries written by Irving, who had developed skill at mimicking Hughes’s handwriting using as a template a sample that had been included in a *Newsweek* article. The forgeries were so skillfully done that handwriting experts authenticated them as genuine. In the letters, Irving had Hughes convey admiration for Irving’s previous work and express the desire to collaborate with him on a book about Hughes’s legendary life.

Cleverly, Irving also had Hughes demand as a condition of his participation in the biographical project that all correspondence be done exclusively through Irving, giving him complete

authorial and financial control over the process. When mounting doubts were raised regarding Irving's veracity regarding the letters, he took a polygraph test, the indeterminate results of which suggested at least the possibility that Irving was not lying.

Irving was aided in perpetrating his hoax by his friend, Richard "Dick" Suskind, and his fourth wife, Edith (née Sommer). Suskind helped conduct the meticulous research required to assure that publicly known facts about Hughes would not conflict with what the invented Hughes said in his interviews regarding what he did and when and where these activities took place. In preparing for the faux interviews, Irving and Suskind conducted extensive archival research, ranging from newspaper articles to unpublished manuscripts. In addition, when possible they sought out and interviewed Hughes's friends and acquaintances. This research provided rich details, some not publicly known, that lent the interviews and the fictional autobiography based upon them a high degree of credibility.

In order to process the money Irving's publisher thought it was sending to Hughes, Irving's wife Edith opened a Swiss bank account under the pseudonym Helga R. Hughes. She visited the bank in disguise to make cash withdrawals, much of which was hidden around the couple's property on the Spanish island of Ibiza.

Clifford and his accomplices were betting that the notoriously reclusive Hughes, who at that time had completely retired from public view for almost 15 years after decades of celebrity, would not come out of his seclusion in order to challenge them. They were wrong. On January 7, 1972, Hughes held an unconventional press conference from the Bahamian hotel where he was then staying, in which he spoke to seven reporters via a speaker placed on a stand and denounced Irving as a fraud and the "autobiography" as a fake. Two weeks later, as evidence against them mounted, Irving and his conspirators were no longer able to plausibly claim that their Hughes's autobiography was genuine. They confessed to the hoax on January 28, 1972, and were subsequently indicted, convicted of fraud in federal court, and then sentenced to prison.

Irving served 17 months of his two and a half year sentence. His wife Helga, who was sentenced

to two years, had most of her sentence suspended and spent just two months in prison. Suskind was sentenced to six months and released after serving only five because of good conduct. Irving returned most of the money he had obtained as a result of his hoax.

Irving's literary hoax has lived on in the imagination of American popular culture. He has written his own book about it, simply titled *The Hoax*. His literary fraud occupies a prominent place in Orson Welles's tongue-in-cheek 1974 documentary essay on artistic authenticity and duplicity, *F Is for Fake*. In 2006, Mirimax released *The Hoax*, a film treatment of the scandal, directed by Lasse Hallström and starring Richard Gere as Irving.

## Islam

According to Islamic theology, Islam is a monotheistic and Abrahamic religion, a message from God revealed to the Prophet Muhammad by the angel Gabriel in the form of a book, the Holy Qur'an, in the 7th century C.E. This new Abrahamic religion was considered necessary because it was argued that the previous Abrahamic holy books (the Talmud and the Bible) had been modified several times and a new religion was a way to return to the truth. Thus, as happens with any religion and from the start of Islam, accusations of lying and deception have been traded and

debated regarding the authenticity of the newer religion and the accuracy of some information in the previous monotheistic ones.

In the modern world, some Muslims, especially in countries where Muslims are a minority, believe they are victims of lies and deception; in their view, their religion, and sometimes the Prophet, are misrepresented internationally due both to misinformation and to the actions of particular Muslims, who do not necessarily represent the faith. Their feelings of alienation and misrepresentation can lead to marginalization and extremism.

In addition, conflicts over authenticity and truthfulness exist within the various sects of Islam. These accusations and debates, which emerged early in the history of Islam, continue today and have serious international consequences. They sometimes become part of propaganda forming the context for war and contributing to moral disengagement; for example, selected passages of doctrine are used by members of one group to justify violent actions that are seen as a violation of fundamental Islamic principles by other groups. In addition, challenging the truthfulness of something held as true, and even as a fundamental part of identity, by the followers of a religion or sect can sometimes ignite strong emotional reactions.

### Islamic Teachings on Lying and Deception

The Qur'an is the main source of Islamic teachings and laws, along with the sayings of the Prophet, called Hadith, and his life style, called Sunnah. Muslims believe that the Holy Qur'an is the literal word of God and that it did not change in any way since the time of the Prophet. Through centuries, honest transmissions of the Qur'an and Hadith have been an essential part of the faith. Muslim scholars, centuries ago, established a whole field of inquiry that investigates the authenticity of a Hadith attributed to the Prophet by examining the moral characteristics of the people in the lineage of transmission of that Hadith in order to determine the likelihood that their reporting was inaccurate.

In addition, the Qur'an teaches that God has attributes and names, and among them is The Truth. In Islamic theology, devotion to the truth is part of the faith. Other attributes and names of God in Islam are The All Seeing and The All

Hearing, The Apparent, and The Hidden. The Qur'an teaches that God knows what is apparent and what is hidden, the secrets, and things that are even beyond secrets. According to the Qur'an, lying and deception might distort the perceptions of people, even of the person doing the deceiving, but they will not change the truth as it is known by God.

Islam forbids lying and deception in all their forms. It forbids lying in personal relations unless it is in the form of complimenting a loved one or reconciliation. It also forbids hypocrisy, falsely accusing someone of something they did not do, denying the power of something or of an event, denying reality or evidence, and denying the truth. It forbids lying about God, as in attributing messages, rules, or attributes to God that were not from God, and lying in religious matters (for example, in the form of sorcery and magic), in business dealings, and in international treaties.

However, Islam permits, with some limits, deception in war; also, according to some Muslim scholars, it allows lying to hide one's real beliefs in order to protect oneself from harm by oppressive powers. This exception is similar to the philosophical principle of choosing the less harmful option when faced with two harmful choices. This concept, known as *Taqqiya*, is a debated and controversial concept among Muslims and others.

### Levels of Lying

In Islam, lying can be carried out by speaking, behaving, or creating illusions in the heart. The Qur'an mentions three levels of lying. The first is lying to bring a benefit or prevent harm to one's self. The second and more serious is lying to harm, to accuse, or attribute something to someone else knowing that it is not the truth. The third and most serious is lying to confuse falsehood with the truth to the point of self-deception wherein one believes one's own lies.

Truth-telling is seen as a form of worship and constructive behavior that gets a person closer to God. Truth-telling in the form of advice is an essential component of Islamic law.

Al-Hasaba or religious authorities are seen, by Islamic law, as practicing truth-telling or advising society following the traditions of the prophets. The Prophet taught that among the closest people

to God in the afterlife is someone who tells the truth to an oppressive ruler. In addition, the word for friend in Arabic is *sadeq*, which means the one who tells another person the truth and believes the other person is truthful.

The Qur'an describes people in heaven as the truthful and honest ones who did not believe the deceptions of Satan. In addition, it talks about efforts by some people to hide or alter the truth by using language and says that some try to deceive God but they only deceive themselves. Thus, the Qur'an is seen by Islamic theology as an effort to free people from the deceptions surrounding them that were made by Satan, various powers, religious authorities, the way history was told, and traditions.

## Jackalope

Jackalopes are imaginary creatures with the body and head of a jackrabbit, topped incongruously with either the spiky antlers of a deer or the pronged horns of an antelope. Their alleged existence—especially in the states of the Rocky Mountain West, Great Plains, and northern midwest—is often the source of good-natured lying, in the tradition of fooling tourists and other persons seemingly susceptible to tall tales and exaggeration. Examples of other such creatures include the fur-bearing trout, hoop snake, and wild haggis, as well as the practical joke to hunt elusive snipe on moonless nights in the woods. These types of purely imaginary creatures are thus distinguished from the Loch Ness Monster, Abominable Snowman (or Yeti), and Bigfoot—all of which have both loyal believers and doubtful skeptics on the question of actual physical existence.

The origins of the jackalope are difficult to determine. According to an obituary in the *New York Times* (2003), the jackalope was created in the 1930s by two brothers who owned a taxidermy shop in Douglas, Wyoming. One day after returning from a hunting trip, Douglas Herrick and Ralph Herrick casually tossed the body of a jackrabbit onto their shop floor. When the rabbit's head serendipitously came to rest against a set of deer antlers, the brothers were inspired

to combine the two unrelated parts into a new hybrid creation. However, other sources maintain that the first jackalope was observed by either John Colter on the Lewis and Clark Expedition in 1807 or 1808 or by Wyoming trapper Roy Ball in 1829 (or in 1862, according to still other sources). Doubters of the Herricks' account also maintain that another store in Buffalo, Wyoming, featured a stuffed jackalope as early as the 1920s.

Other theories suggest that the American jackalope may derive in part from real European rabbits bearing horn-like appendages as early as the 16th century. One such rabbit, identified in German as *die gehörnten Hase* (the horned hare) and in Latin as *Lepus cornutus*, was illustrated in Konrad Gesner's *Thierbuch* (or *Animal Book*, 1563). Subsequent illustrations of rabbits with small horns growing out of their foreheads appeared in other printed volumes throughout the 17th and 18th centuries in Europe. Wildlife biologists and naturalists have speculated that these rabbits were infected with the Shope papilloma virus, which causes large warts resembling horns to grow on the heads of rabbits. This same virus has also infected cottontail rabbits in the United States, particularly in the Midwest and Great Plains. Still another hypothesis tracing jackalopes to Europe is that immigrants to the United States may have brought with them knowledge of imaginary animals with antlers, wings, fangs, and a tail—all attached to

the body of a small mammal that resembles a rabbit or squirrel. In Bavaria, this composite creature is known as the *Wolpertinger*. In neighboring Austria, it is called the *Raurackl*.

Whatever its origins, the jackalope is now associated with a wide variety of exaggerated attributes. According to this lore, jackalopes are fierce and elusive creatures, capable of hopping at speeds greater than 65 miles per hour (which would place them second only to the cheetah among the world's fastest animals on land). Reputed to be highly intelligent and cunningly deceitful, jackalopes are supposedly able to mimic any sounds, including those of coyotes, crows, and humans, and even know how to project their voices like ventriloquists in order to fool hunters on their trail. There are also reports of jackalopes being able to imitate the sounds of crying babies, the accents of French speakers, and the lyrical ballads of cowboys and lumberjacks—albeit only on dark nights before an advancing thunderstorm. Additional lore maintains that the elaborate mating ritual of jackalopes occurs only amid flashes of lightning (according to one source), or during the fall migration, after the young have been kicked out of the nest and left to fend for themselves (according to another source).

The city of Douglas in eastern Wyoming—where the Herrick brothers lived and worked—calls itself “Home of the Jackalope” and claims more jackalope-related activities and enthusiasm than any other municipality. For instance, the annual Jackalope Days Celebration takes place there in early June; images of jackalopes adorn municipal structures and vehicles, and statues of jackalopes abound, including one that is eight-feet tall in Jackalope Square in the center of Douglas. (Other large jackalope statues are found in Red Lodge, Montana; Wall, South Dakota; and Fort Worth, Texas.) In both 2005 and 2013, the Wyoming House of Representatives passed bills to establish the jackalope as the state's official mythical creature, but the Wyoming Senate has not yet approved the legislation.

Throughout Wyoming and neighboring states, tourists have been able to purchase a variety of jackalope memorabilia for at least 70 years. These novelty items include tall-tale postcards featuring images of jackalopes (sometimes with humans riding astride them); mounted trophy heads of

*The jackalope, a humorous example of what folklorists have labeled “tales of lying,” is associated with a wide variety of exaggerated attributes such as hopping at speeds faster than 65 miles per hour, having the capacity for cunning deceit, and having the ability to mimic any sound.*

jackalopes; cans of jackalope milk; and nonresident permits for the hunting of jackalopes, albeit valid only one day each year, on June 31, between the hours of midnight and 2:00 A.M. (in some versions) or between sunrise and sunset (in other versions). Curiously, several of these permits require that jackalope hunters be absolutely truthful, except when questioned about their experiences with jackalopes.

Because the stories and claims about jackalopes are typically told with tongue firmly in cheek, they do not represent intentional lying or deception, any more than do the stories about Santa Claus or the tooth fairy. Nevertheless, the jackalope narratives are splendid examples of what folklorists

have labeled “tales of lying” or tall tales. Told either as first-person narratives or as second-hand accounts in which the narrator knows the individual(s) involved, tall tales are celebrated for their inventiveness and exaggeration, the more outlandish, the better, especially when related to great exploits of hunting and fishing. The best tall tales are often those that are circulated from person to person in oral tradition, which may help explain why there are so many varied accounts of jackalope history and lore.

a successful military career, fought in duels, and became a wealthy lawyer. Jackson later entered into politics, rising from poverty to become the nation's first frontier president. His presidential legacy is a controversial one, stemming from his decision to remove five Native American tribes from their southeastern homes and relocate them in the western United States. Many contemporary historians refer to this policy as an “ethnic cleansing” of the tribes, and they denounce the deception with which Jackson and other federal officials forced Native Americans to abandon their homelands.

Jackson was born on March 15, 1767, to Scottish-Irish immigrants Andrew Jackson and Elizabeth Hutchinson Jackson in the Waxhaws border region between North and South Carolina. He was the couple's third child; however, Jackson's father died in an accident three weeks before his birth. Jackson received little formal education, entering into a local militia as a courier at the age of 13. During the Revolutionary War's Battle of Stono Ferry on June 20, 1779, Jackson's eldest brother Hugh died from heat exhaustion. Jackson and his brother Robert were captured by the British and held as prisoners, both contracting smallpox. Robert died before their mother could secure their release. She volunteered her time as a nurse to prisoners of war during outbreak of cholera. Elizabeth died from the disease, leaving Jackson an orphan.

Jackson blamed the British for the deaths of his mother and brothers. Jackson later moved to northeast Tennessee, beginning his legal career. In 1796, he was elected a delegate to the Tennessee constitutional convention and in the following year was elected a U.S. senator as a Democratic-Republican. Jackson later resigned from the Senate and was appointed judge of the Tennessee Supreme Court. In addition to his legal career, Jackson had a successful career in the military, eventually becoming a war hero to the nation. Jackson fought in the War of 1812, defeating the Creek Indians at the Battle of Horseshoe Bend. He was appointed commander of the Tennessee militia, serving as major general. After the war, Jackson fought off British forces that were threatening New Orleans. He became a national hero because of his victory at the Battle of New Orleans, receiving a gold medal and thanks from Congress. In

## Jackson, Andrew

Nicknamed “Old Hickory” for his toughness and aggressive personality, Andrew Jackson was the seventh president of the United States. He had

December 1817, Jackson ordered an invasion of Florida. His troops captured Spanish posts, claiming the surrounding land for the United States.

### Seeking the Presidency

Jackson's popularity eventually led him to run for president in 1824. Although he won the popular vote, he did not become president. The election of 1824 was the first time in U.S. history that no presidential candidate received the majority of electoral votes, leaving the House of Representatives to decide among the candidates: Jackson, Secretary of State John Quincy Adams, Secretary of the Treasury William H. Crawford, and Speaker of the House Henry Clay. Crawford was out of the race after suffering a stroke and becoming critically ill. Clay gave his support to Adams and later became Adams's secretary of state, an arrangement that Jackson's supporters dubbed the "corrupt bargain."

Jackson continued his quest for the presidency in 1828, defeating incumbent John Quincy Adams. During the campaign, there were several personal attacks made by opponents against Jackson and his wife, Rachel. Before his inauguration in 1829, Rachel suddenly died, leading Jackson to say that he would forgive those who insulted him but never forgive those who attacked his wife.

One of Jackson's accomplishments during his eight years as president was paying off the entire national debt. This was the first and only time in U.S. history that the debt had been eliminated. Jackson opposed the Electoral College and also encouraged the growth of the spoils system. He distrusted banks and believed they had too much power, leading him to shut down the Second Bank of the United States by vetoing its recharter Congress in 1832 and withdrawing funds from the bank the following year. The Nullification Crisis was also a period of contention in Jackson's presidency. South Carolina was against the Tariff Act of 1828, arguing that it was unconstitutional. Jackson declared that states did not have the right to nullify federal laws. Despite these accomplishments, Jackson's legacy remains tarnished by the policy he enacted against Native Americans.

### Native American Removal

In 1823, the U. S. Supreme Court handed down a decision that allowed Native Americans to

occupy their lands but to hold no title to them. Five Native American nations—the Cherokees, Creeks, Choctaws, Chickasaws, and Seminoles—were called the Five Civilized Tribes, using nonviolent means to resist white settlers' encroachment on their lands. Jackson, however, was a forceful proponent of Indian removal, negotiating nine out of the 11 treaties that stripped tribes in the southeastern United States of their homelands. As white settlers continued to move to this area, they pressured the federal government to acquire the homelands of the five tribes.

In 1827, the Cherokee nation adopted a written constitution, declaring themselves a sovereign nation in an attempt to safeguard their rights. The state of Georgia, however, did not recognize the tribe's sovereignty and passed a series of laws that denied the Cherokees their rights, hoping that these laws would encourage the tribe to leave the state. In 1830, the Cherokees asked the U.S. Supreme Court to issue an injunction, arguing that the state of Georgia had adopted laws aimed at "annihilating" the Cherokees as a "political society." The Cherokees claimed the court had the jurisdiction to hear the case because the tribe was a "foreign nation." In its ruling in *Cherokee Nation v. the State of Georgia* (1831), The Supreme Court denied the injunction, maintaining the Cherokees were not a "foreign nation" as defined by the U.S. Constitution and therefore the court lacked original jurisdiction to hear the tribe's case.

In 1830, President Jackson signed the Indian Removal Act, giving him the power to negotiate treaties with Native American tribes who would be removed to federal land west of the Mississippi River in exchange for abandoning their homelands. The removal was to be peaceful and voluntary, but these claims proved to be deceptive. In actuality, Jackson forced the southeast nations to leave after they resisted.

The Choctaws were the first to sign the land removal treaty, and for the next 28 years the government struggled to force the relocation of the remaining southeast nations. A small group of Seminoles was coerced into signing the treaty, causing the majority of the Seminoles to declare the treaty illegitimate. The Seminole's were finally paid to move west, following the Third Seminole War (1855–58).

The Creeks never signed the removal treaty, leading the secretary of war to order their removal in 1836. The Chickasaws signed the treaty in 1832, migrating to the west in the winter of 1837 to 1838. The Cherokees were tricked with an illegitimate treaty, and only a small group of Cherokees agreed to sign the agreement. The Cherokee nation was eventually given two years to voluntarily migrate, and by 1838 only 2,000 people were left in their original homeland. The U.S. government sent 7,000 troops to remove 16,000 Cherokees, who then marched to the west on what is now known as the Trail of Tears; 4,000 Cherokees died from hunger, cold, and disease during this journey.

By 1837, the Jackson administration was responsible for locating 46,000 Native Americans from their homelands to the west. According to historians, Jackson's role in these events continues to garner criticism. Jackson negotiated nine of the 11 treaties, which stated that the federal government would protect the tribes until they moved. However, the U.S. War Department backed down on their promise, leaving the tribes to fend for themselves against the onslaught of white settlers. Jackson described Native Americans as children in need of guidance, claiming the removal policy would be beneficial to them. Some Americans felt that the policies were deceptive, protesting that it was an excuse to justify an inhumane and brutal course of action. To date, the treatment of Native Americans by the Jackson administration remains a controversial and disheartening chapter in U.S. history.

Jackson died in Nashville, Tennessee on June 8, 1845, at age 78.

## Jefferson, Thomas

The American experiment that had its genesis on July 4, 1776, gave birth not only to a unique nation but also to a unique collection of historically significant leaders known as the Founding Fathers. In the top tier of that group is Thomas Jefferson, master statesman and principal architect of the Declaration of Independence. In that benchmark document, Jefferson spoke of "Nature's God," the "Creator," and that "all men are created equal." From those famous words and other pieces of evidence, many have drawn the conclusion that Jefferson stood in the historic stream of Christianity and that the faith of all Founding Fathers was distinctly Christian and opposed to the practice of enslaving people. A new nation was created based on individual freedom and a democratic republic, but the Declaration did not extend "life, liberty, and the pursuit of happiness" to all people; some were excluded. Embodied in Jefferson is a model of subtle deception rather than the more crass practice of lying. It is a dual deception involving faith and practice, perhaps more for political than personal reasons. Some of the Founding Fathers, of the same mind as Jefferson and seeking a measure of approval from the populace in order to achieve success in this new experiment, are cast in the same mold.

### A Deceptive Paradox

Arguably, the majority of the people living in the colonies were Calvinist Christians of one kind or another, as demonstrated by their respective state constitutions by the time of the American Revolution. However, some of the Founding Fathers, including Jefferson, were not Christians. They were Deists or Unitarians influenced by the European Enlightenment, who rejected as unreasonable the primary doctrines of the Christian faith. Jefferson rejected the Anglican Christian faith in which he

had been raised and declared himself to be a “free-thinker” and essentially in a religious category of his own making. He denounced the traditional theology of Anglicanism as blasphemous and rejected the historic Christian doctrine of the Trinity as an absurd impossibility that no rational man could accept. Even though Jefferson held Jesus in high regard as a moral teacher, he rejected him as the Savior God, which is the platform of Christianity. However, his rejection of the traditional Christian faith was not overtly antagonistic or public, which created a deceptive and persuasive paradox. Jefferson often identified himself as a Christian, which some historians, especially Evangelicals, point to today as proof that he was a Christian. Jefferson could comfortably refer to himself as a Christian as long as that self-identification was understood according to his own definition of what constituted the “real” Christian faith.

Consistent with his own personal dialectic involving faith and in concert with the majority of the Founding Fathers, Jefferson moved to the forefront in the movement that eliminated officially established ties between the newly formed government and all religious denominations. This tension was written into the First Amendment of the Constitution, which prohibited Congress from passing any law that establishes a certain religion, while at the same time allowing the free exercise of any and all religions. Later, in 1802, in a letter to the Connecticut Baptists, Jefferson famously explained the First Amendment as erecting “a wall of separation between church and state,” clarifying the intent that it was not to be understood as being hostile to religion but as guaranteeing the freedom of all religions by not favoring any particular one. The paradox of Jefferson’s personal faith finds a direct correlation in the debate over whether the intent of the Founding Fathers was to create a distinctly Christian nation—or not.

### Slavery Contradictions

In spite of Jefferson’s desire to nurture a public image as a morally upright Christian who declared that “all men are created equal,” his record on the issue of slavery could only be described as contradictory. At times he publicly opposed the slave trade and spoke of its destructive effects on society, yet throughout his life he owned over 200 slaves at any given time who labored on his

numerous plantations in Virginia, with about 130 at Monticello alone. In his entire span as a slave owner, Jefferson only freed a handful. In his original draft of the Declaration of Independence, he denounced slavery in the strongest terms, calling it a “cruel war” against mankind. His denunciations were later redacted, and a few short years later in the 1790s his emancipation efforts virtually ceased. He proposed federal legislation banning slavery in the new territories west of the colonies, yet he opposed the practice of slave masters freeing their own slaves by preventing a slave-freeing law (manumission) from being enacted in the Virginia Assembly in 1769. As president, he refused in 1804 to recognize Haiti as a new republic because it was established by a slave rebellion. Yet in 1807, he signed a bill prohibiting the United States from participating in the international slave trade.

An ancillary deception running parallel to the slavery issue involves the question whether Jefferson had fathered many out-of-wedlock children, a significant stain on one’s reputation at the time that was made more egregious if the woman was the father’s slave. This issue drew national attention, and apparently Jefferson denied the affair. A historian of the time published the claim of Jefferson’s grandson that it was another member of the family who fathered the children. Subsequent historians and the general public adopted that view for over 180 years. However, in 1998, the results of DNA analysis conducted at the University of Virginia were significant enough to conclude that Jefferson had indeed fathered several children with his slave Sally Hemings, thereby shifting the consensus away from believing the deceptive denial and placing Jefferson in a less favorable light.

## Johnson, Samuel

Samuel Johnson was one of the most significant literary figures in 18th-century English literature and indeed all of English literature. His justly celebrated *A Dictionary of the English Language*, published in 1755 and a product of nine years of work, is considered one of the great monuments to the language and a tremendous feat of scholarship. His seemingly humdrum life in London was immortalized by James Boswell, whose *The Life of Johnson* (1791) is both hugely entertaining and a source of citations of vintage "Johnsonia," that is, selections of quotes gleaned from conversations with the famous man and from his other intimates. While some scholars consider Boswell unreliable and prone to exaggeration

and self-promotion, his work remains among the most accessible points of entry to approaching and understanding Johnson and his era.

### Early Life

Johnson was born in Litchfield, England, in 1709 and came from a middle-class background. His father owned a bookstore, and Johnson's home was a highly literate household that had fallen on hard times. Johnson acquired a severe case of scrofula as a child, which left him scarred for life and demonstrating traits of depression. More visibly and personally distressing to the young Johnson was that he involuntarily made movements, gesticulations, and loud verbal tics that made some contemporaries think him "an idiot" or deranged. Twentieth-century scholars are relatively sure that these traits are manifestations of Tourette syndrome. However, this seemingly obvious diagnosis (from a modern point of view) was not made until 200 years after his death and was no help to Johnson in his lifetime. Consequently Johnson was often a figure of fun to children and street people as he traversed London on his many rambles.

Although Johnson's condition was disconcerting to those who met him, his powers of the mind and conversational skills were such that such prejudices were quickly banished. Though a fine student, lack of funds forced him to quit Pembroke College, at Oxford University, after only one year. After a failed stint as a teacher (he later admitted he had no facility for teaching) he became a tutor and tried his hand at writing.

In 1735 he married Elizabeth "Tetty" Potter, a wealthy widow who was over 20 years his senior. The marriage was not popular with her family, and the couple eventually lived apart for much of their relationship. His wife is alleged to have sunk into opiod addiction and alcoholism and took to her bed. Nonetheless, her early death in 1752 led Johnson to a sense of guilt and sadness, and he never remarried. In 1737 he moved to London, where he wrote biographies of famous literary figures, essays, and several famous poems, one memorializing his beloved London. He famously said that "if one tires of London, one tires of life."

### Fame

In 1746, a publisher and a group of literary figures petitioned Johnson to write an authoritative

dictionary. This task would take almost a decade, but it gained him fame and some economic benefits. After publishing his dictionary in 1755, he wrote hundreds of essays and a celebrated annotated collection of works by William Shakespeare. By the mid-1760s he was a celebrity, with London newspapers following his coming and goings and speculating on his next move. He became a much-desired dinner guest because of his fame, brilliant conversation, and pithy quotes. Although his literary output is impressive, he was famous in his own time for not enjoying writing, preferring to eat, drink, and converse with his intimates. He especially enjoyed the company of attractive women but was atypical among male contemporaries, as he was famously ethical and puritanical in his relations with them.

Receiving a generous pension in 1762 from King George III allowed Johnson more time to devote to finishing his encyclopedic edition of Shakespeare. In 1763, he formed The Club with several British worthies, including the painter Sir Joshua Reynolds, the politician Edmund Burke, the actor David Garrick, and writers Adam Smith and Edward Gibbon. This group met weekly at a pub where they enjoyed good drink, food, and, no doubt, stimulating conversation.

In 1765, he was introduced to the Thrale family, with whom he was to live for almost two decades. When Henry Thrale, a wealthy brewer, died in 1781, Johnson, who had been a widower for some time, may have hoped to marry his widow, Hester, but they became estranged when she became infatuated with an Italian music teacher whom she eventually married. Johnson was desolated by these developments. However, Hester Thrale's book and correspondence became critical sources for Johnson scholars.

Late in life, in 1773, an arduous trip to Scotland with his friend and biographer, Boswell, gave rise to *A Journey to the Western Islands of Scotland*. At this time, as a Tory and admirer of the king, Johnson vigorously defended British policy toward the restive North American colonies in a variety of pamphlets and in conversation with policy makers of the day. He also produced more literary works and supported a small household of intimates. He died in 1784 shortly after suffering a stroke.

### Johnson and Truth

Johnson was no stranger to deception. When first coming to London he manufactured debates in Parliament for a newspaper that were more eloquent than the words that were spoken by the real politicians. But thereafter he became a crusader against deception, fraud, and lying. His critique of falsehood and deceit was based on his posture as a debunker. However, Hester Thrale wrote that more fundamentally, "his ruling passion may be said to be a love of truth."

It was also noted that Johnson was honest in even the most trivial of situations. One writer says that his career amounted to "a prolonged assault on falsehood." Johnson believed that deception and fraud weaken society and faith. Most important he believed that fraud creates a distrust that destroys confidence and harms the collective tendency toward charity. That is, once faith in general is brought into question, reverence, trust, and generosity can never be fully restored.

In *The History of Rasselas, Prince of Abissinia* (1759), Johnson states that, "All imposture weakens confidence and chills benevolence . . . The distrust, which he can never afterward wholly lay aside, may stop the voice of counsel, and close the hand of charity." More concretely, "Whoever commits a fraud is guilty not only of the particular injury to him whom he deceives, but of the diminution of that confidence which constitutes not only the basis but the existence of society."

He also famously attacked the contemporary literary fraud known as Ossian. In 1760, the author James MacPherson claimed to have gathered authentic oral literature and written sources for archaic Scots epic poetry. This claim was taken seriously by many literary lights and gave rise to nationalist poetry and epics throughout Europe. However, time has proven Johnson to be correct; Ossian was a creative fabrication, or "fakelore."

## Judaism

Judaism views honesty as crucial for both collective social function and individual moral integrity. Truthfulness is crucial within the Jewish legal system, in which dishonesty and deception is forbidden. Habitual lying and lying to children are also always forbidden. Dishonesty, however, is permitted, viewed favorably, and even required in certain situations. Jewish beliefs regarding truth (*emet*) and dishonesty are taken from the Torah and the Talmud as well as from Jewish tradition. Situations that allow for untruthfulness include the preservation of peace, respect for another person, and the protection of one's humility, modesty, property, and life.

The Torah comprises the written text of the first five books of the Bible, which God gave to Moses. The Talmud consists of the written compilation of oral commentary on the Torah given to Moses simultaneously with the written Torah, as well as historical rabbinic commentaries on the Torah. The Talmud and other Jewish commentaries discuss both Jewish legal matters (*Halakha*) and the broader Jewish tradition, including ethics and folklore. Scholarly religious commentaries, such as the Talmud, form an important component of the Jewish tradition, serving as guidelines linking eternal religious values such as truthfulness with everyday life.

The Talmud and post-Talmudic rabbinic commentaries interpret historical and biblical examples of lying and deception to extract scholarly interpretations of Jewish guidelines regarding truthfulness and lying. While truth is an essential

guiding principle within Jewish law, religion, and tradition, Judaic scholars acknowledge the commonality of dishonesty in everyday life. Judaic scholars recognize the need to make historical and biblical teachings on truth relevant to new generations and the realities of the modern world. They also struggle with situations in which truth comes into conflict with other, equally important Jewish values.

The Talmud emphasizes the importance of truth as a central attribute ascribed to God within the Torah, stating that the "seal of God is truth." Truth is a personal attribute to be emulated by God's people as a dynamic way of life rather than a universal value. Truth is an essential component of one's relationship to God and an essential component of the final judgment, when one must account for one's life. Liars, on the other hand, are categorized among those who are not worthy of God's presence. Truth also aids in the fulfillment of *tikkun olam*, the general belief in the restoration of the world through positive deeds and commandments known as *mitzvot*.

Judaism views truthfulness as more than simply the accurate statement of facts or the philosophical conflict between objective universal natural laws and mankind's subjective perception of the world. Truth is a dynamic, highly personal, all-encompassing guideline for living that shapes one's character and should inform all aspects of a person's life and decisions. The Talmud also emphasizes the importance of truth in everyday life, noting that habitual liars will quickly lose people's trust. Some scholars note that the Hebrew word for truth, *emet*, includes the first, middle, and last letters of that alphabet to highlight its all-encompassing nature.

The Torah contains several clear proscriptions against untruthfulness within the Jewish legal system, including the proscription to distance oneself from a false matter (Exodus 23:7), as well as prohibitions against bearing false witness (Exodus 20:16) and against theft, false denials, and lying (Leviticus 19:11). The applicability of these proscriptions to nonlegal matters, however, is debated. Scholarly commentaries also debate whether the Torah prohibits dishonesty that does not negatively affect another person. The Talmud recognizes that certain situations allow for or require dishonesty even if the proscription

to distance oneself from a false matter is taken to encompass all types of lies and not just those within the judicial system.

The act of lying has been interpreted as an attempt to seek favor with man as opposed to God and even as an outright rejection of God, whose seal is the truth. The Talmud further states that when a person enters the final judgment, the honesty of his or her interactions will be the first question they will have to answer. While the overall Judaic emphasis is on honesty as an imperative value within Jewish law and tradition that should be practiced as an integral part of Jewish life, scholars do acknowledge situational exceptions to this rule.

### Situations Allowing Deception

Judaic scholars have debated the meaning of the stories and commentaries regarding Jewish values such as honesty within the Torah and the Talmud for centuries. The Torah and Talmud both recognize that truth sometimes comes into conflict with other ethical values emphasized within the Jewish tradition, such as justice or peace. Even Judaic scholars that agree on the permissibility of lying in a given situation often debate whether there is a further obligation to lie or whether such a lie constitutes a *mitzvah* (positive deed). The Torah allows for lying when no harm to others is caused, while the Talmud forbids all types of lies with leniency in certain situations.

Permissible lies generally include those told with positive goals in mind, such as peace or comfort; those that protect modesty, humility, and dignity; those that will prevent harm or embarrassment to another; or those told when other options have been exhausted. Lying is also permissible in situations where there is no benefit to be realized in stating the truth, or when the person being lied to is unscrupulous and therefore an honest answer is not required. Some types of permissible lies are clearly defined while other situations are less clear and thus are subject to more varying interpretations within the commentaries.

One category of permissible lies includes those lies told in the interest of seeking or maintaining peace. The Talmud comments positively on a number of examples in which historical or biblical figures lied in order to preserve peace. One of the most well-known examples from the Torah

involves God deliberately changing the words spoken by Sarah noting the old age of her husband Abraham so Abraham will not learn the true nature of Sarah's remarks. Examples given from everyday life include that of a person separately informing people involved in a dispute that the other is sorry in order to facilitate reconciliation. There is disagreement as to whether lying in the interest of peace is simply permissible or is actually a requirement and/or a *mitzvah*. Lying to peacefully resolve a pre-existing situation is viewed more favorably, while lying to prevent a future problem from arising is more controversial.

It is also acceptable to lie in order to protect another person from harm, inconvenience, or embarrassment. A commonly cited and debated example is the argument over what is acceptable to say to a bride on her wedding day, when it is considered a *mitzvah* to make the bride happy. It is agreed that one should "dance before" (praise) the bride, but commentators dispute as to what exactly should be said. Other cited examples include downplaying a host's hospitality to prevent him from being overburdened by additional or unscrupulous guests; avoiding or concealing facts that will violate another's privacy or cause them embarrassment; or hiding the truth from the severely ill, whether regarding their own health or other matters that may upset them and thus further jeopardize their health.

Another category of acceptable motives for lying is that of the preservation of humility and modesty and the prevention of embarrassment. The Talmud presents a number of examples bearing the interpretation that rabbinic scholars may lie to deny knowledge of specific Talmudic tracts with which they are familiar or to deny marital sexual relations in the interest of humility and modesty. Other interpreters state that those who ask questions regarding marital relations are not scrupulous and are therefore undeserving of truth. Some commentators argue that these exceptions apply to all people and are not just exclusive to such scholars.

Lying to protect or recover one's property from the unscrupulous or illegitimate is considered permissible. A commonly cited example within the Talmud is telling thieves or unscrupulous tax collectors that one's produce is royal property or *terumah*, a special category of produce

that may only be consumed by priests, so they will not wish to seize it. Talmudic scholars also argue that unscrupulous people as a whole do not require truthful answers or dealings because of the dishonesty of their very nature. Commentaries are in less agreement with regard to other types of extenuating circumstances involving one's property, such as lying in order to recover money owed.

The Torah and Talmud also note other cases in which lying may be acceptable. These include the commonly practiced use of exaggeration, when it is quite clear to the listener that the statement is not literally true and the speaker's intent is not to deceive but to educate or emphasize a point. Some commentators argue that one may use lies such as the false attribution of a statement to a notable person if such dishonesty is viewed as the only way to gain support for a matter involving *halakha* (Jewish law) because of the importance of maintaining the Jewish legal tradition.

The Talmud also debates questions of honesty and deception within business. Examples of deceptive business practices include misleading descriptions of the quality of a good or service, making a business deal appear better or worse than it really is, lying about a good's cost to the merchant or the interest or price offered by another potential buyer, and the use of deceptive techniques to improve a good's appearance. More debate occurs when the situation involves a seller's change of an earlier verbal commitment to a purchase price at the time of actual sale. Some feel it is acceptable if there are certain extenuating circumstances, such as a change in market prices between the verbal commitment and actual sale, while others feel that an honest seller must stand by his earlier word.

One of the most serious situations involving uncertainty over the ability to lie in extenuating circumstances is the opportunity to save a life. There are three sins that a Jew may not commit in

*Legalman 2nd Class Justin M. Wiser reads from a prayer book during a Jewish Shabbat service in the chapel aboard the aircraft carrier U.S.S. George H. W. Bush, August 12, 2011. Jewish beliefs regarding truth (emet) and dishonesty are taken from the Torah and the Talmud as well as from Jewish tradition. While Jewish law forbids dishonesty and deception, and habitual lying and lying to children is always forbidden, dishonesty is called for in certain situations such as preservation of peace and respect for another person.*

order to save his or her life: murder, idolatry, or an illicit sexual relationship with a close relative. All other sins, including lying, may be committed when one's life is at stake. More controversial special circumstances of lying to save one's life that have received lengthy debate include the outright or implied denial of one's Jewish faith. It is generally permissible within Jewish law to commit a sin in order to save one's own life, but it is less clear as to whether this ability applies to opportunities to save another person's life.

The Talmud and other Jewish commentaries provide interpretations not just of situations in which dishonesty is acceptable or required, but also interpretations as to how to lie when confronted with such situations. Half-truths and vague or deceptive statements that have multiple interpretations are preferable to outright lies. Some commentators argue that an individual is not held responsible for another's misinterpretation, even if the individual's statements are deliberately misleading. Others argue that deliberately misleading a person violates proscriptions against the theft of another's mind.

Cases in which lying is acceptable come with their own sets of extenuating circumstances that further limit or direct permissible dishonesty. Situational lying is permissible, whereas habitual lying is proscribed, even within the boundaries of acceptable dishonesty. Lying when no one is harmed is permissible within the Torah but not within the Talmud unless an exceptional circumstance is present. The Torah allows for no lying in which personal financial benefit would be realized regardless of the extenuating circumstances.

There are also cases in Judaism in which one may never lie, regardless of the circumstances. One may not lie to a child regardless of the situation so as to avoid training the child to lie. The Torah and Talmud emphasize the importance of total honesty within the legal system. Thus, situational lying allowed within everyday matters is strictly prohibited within the legal system. One should also always remember the seriousness of lying and generally avoid dishonesty when the negative effects outweigh the positive effects, or in an unclear situation in which one doubts if the rules allowing situational lying are applicable.

Judaism views truth as a dynamic concept that should serve as a guiding principle within all

aspects of daily life and for all of one's decisions, whether expressed through words or deeds. Truth is one of God's key attributes, while dishonesty breeds distrust among others and distances one from God. Dishonesty, even in allowable circumstances, is not to be taken lightly. Fear of God's disapproval is seen as the best preventative measure of excessive leniency where the possibility of dishonesty is concerned.

## Justice

Justice is a social judgment that cannot be defined in the same way as tangible objects such as a fruit or tree. It consists of social rules or norms concerning such issues as what is acceptable behavior, how people should treat one another, and how to make decisions affecting others. These rules, shared within a culture or group, facilitate social life and efforts to achieve personal and common

goals. While many think of justice in terms of formal legal institutions or distribution of resources within a country, scientists study the operations and perceptions of justice at levels as small as individual dyads and as large as whole countries, examining issues such as fair treatment of citizens within a society, the operation of formal legal systems, the treatment of members of social groups or businesses, or negotiations between friends or romantic partners.

Recent justice studies have even extended to relationships among animals. Referred to as “wild justice,” nonhuman social justice has attracted interest from a broad range of academic disciplines, such as biology, ethology, psychology, anthropology, and even philosophy. Primates in particular have been known to engage in social justice behaviors including reciprocity, conflict resolution, retribution, and punishment for cheaters and inequity.

The basic goal of justice is to promote social cooperation and success among individuals and the group as a whole. For social rules of justice to effectively guide social interaction between individuals and in groups, there must be consensus concerning principles of justice, participants must accept these principles as guides to social decision making, and the rules must be enforced by the relevant community. But where do these principles of justice come from?

### Justice Concepts and Religion

Some notions of justice may be hardwired by evolution, as may be suggested by studies of animal justice. But many of these ideas are taught and vary substantially between cultures. Religion often forms the basis of notions of justice, and religious doctrine is often intertwined within justice systems. Some countries use religious doctrine as a foundation for laws. In both Saudi Arabia and Iran, Sharia or Islamic law forms the foundation for justice systems. Sharia law is based upon the Qur'an; the Sunnah, or the writings of Muhammad; and the Hadith, the written form of the sayings of Muhammad.

Other countries use religious doctrine as a supplement to established judicial systems. For example, Pakistan's judicial system is based on English Common Law because it was once a part of British India, but it is also heavily influenced

by Islamic law because of the influence and pressure of Muslims in the country. Even westernized secular notions of justice, which try to define justice outside of religion, are nevertheless shaped by ideas from religion. In the United States, for example, much of the justice system has been shaped by Jewish and Christian beliefs.

### Types of Justice

In simple terms, justice might be considered a person “getting what he deserves.” But the philosophy and science of justice has taken a more nuanced approach, distinguishing between several specific types of justice. Moreover, the literature has widely addressed two fundamental issues. First, is the ideal of justice itself deceptive (or unattainable) given the role of flawed human agents in pursuing it? Second, what flawed procedures, deliberate deceptions, and biases and mistakes of judgment contribute to failures of justice? The following are five different types of justice:

*Retributive justice.* All social groups create rules, many in the form of laws, and enforce them by punishing those who violate them. The study of retributive justice concerns principles defining appropriate punishment for wrongdoing. Members of the community typically take action to enforce formal and informal group rules, even when not personally affected by a violator's behavior and often at the risk of personal sacrifice. The need for retribution is driven by the importance of social rules for successful cooperation and functioning of society and may serve the purposes of deterring future wrongdoing or incapacitating the perpetrator (such as by fines, imprisonment, or death). Acts that appear to show blatant disrespect for persons or societal rules or norms, and that threaten the goals of successful social functioning, are viewed as more reprehensible and tend to evoke harsher punishment. If an individual either lies or uses deception to avoid punishment, they would be considered to be behaving unjustly and to be obstructing justice.

*Restorative justice.* Reparations given to a victim of an injustice in the form of money or other benefits are referred to as restorative justice. Restorative justice does not typically involve harsh punishment of the offender. Instead, restorative

justice involves a balancing of “wealth” until the two parties are back in equilibrium. Restorative justice in many countries is litigated in civil courts, where the injured party may sue the injuring party for damages. In some cases, restorative justice is not possible because of the magnitude or type of injury. No amount of money, for example, may compensate for a death caused by the offender. But if the death were caused by noncriminal means, the perpetrator would remain within the civil court system, where compensation would be financial (restorative) rather than imprisonment (retributive).

*Distributive justice.* Rules of distributive justice indicate who should receive what and, as with other forms of justice, may vary considerably. Societies vary in the degree to which resources are available selectively to a privileged few rather than distributed equitably to all. Such inequalities can range from relatively minor financial disadvantage, to extreme disparities of wealth, to fundamental rights to life versus death. Inequalities may reflect differences in social power, or may reflect specific rules of distributive justice, such as when businesses may determine salary based on seniority versus merit or equality.

Scientific studies of justice arguably began with the study of relative deprivation, referring to perceptions of unfairness resulting when an individual or group is receiving less than a relevant reference group. This notion is central to theories addressing perceptions of fairness, satisfaction, and social actions, such as the development of labor unions, social and political protests, and job turnover. Modern theories of distributive justice assume that fairness is assessed by comparison of one's own outcomes to what one believes is “deserved” and offer principles by which deservingness tends to be determined.

One commonly endorsed principle of fair distribution is that of equity, whereby rewards are distributed according to the magnitude of one's efforts or the value of one's contribution relative to those of others. Other prominent principles are those of equality (each receives the same rewards) and need (each receives according to need). Which principle is chosen will depend in part upon whether the goal is to promote productivity, social harmony, or social welfare, respectively and

on relationship characteristics such as cooperativeness, power equality, formality, and whether the situation is social or task-oriented.

A surprising result of research on distributive justice has been the finding that both those who receive less and those who receive more than they deserve react negatively. The greatest satisfaction occurs among those who receive what they think is fair. Those who receive more often object, work harder to feel more deserving, pressure others to redistribute resources fairly, and incur material losses to promote fairness, even leaving a more profitable situation for one with fewer rewards but greater fairness. It appears that people prefer a balance between self-interest and social justice that will not put them at a disadvantage but will likewise not disadvantage others, provoke anger, and destabilize social relations. Relationship dissolution is indeed a risk of violations of distributive justice. People leave situations that violate perceptions of fairness, including jobs, clubs, friendships, and romantic relationships, among others. Unfortunately, such situations are common, because each person's evaluations of his or her own needs, contributions, and deservingness are likely to be self-deceptive and exaggerated by self-serving biases that can undermine agreement on who might deserve what.

*Procedural justice.* Procedural justice refers to the fairness of the process used in making decisions. Seven features are considered crucial to procedural fairness: (1) how the personnel involved are selected, (2) the establishment of ground rules, (3) how relevant information is collected, (4) the decision-making structure, (5) safeguards to ensure the integrity of the procedures, (6) appeal mechanisms, and (7) mechanisms of change. Procedural justice appears to trump distributive, retributive, and restorative justice in that when the procedures by which outcomes are determined are perceived as fair, unfair outcomes themselves are generally better tolerated. A sense of procedural justice allows people to accept decisions even when they do not get what they want.

Procedural and distributive justice have been widely shown to jointly affect perceptions of fairness, which in turn affect such outcomes as job or relationship satisfaction or turnover, among others. Procedural justice also affects perceptions

of the legitimacy of entities such as government, police, courts, or other groups, and behavioral reactions such as cooperation, adherence to agreements, compliance with the law or its agents, prison riots, revolt, or civil disobedience.

*Interactional justice.* Among the most important features of procedural justice, interactional justice refers to the dignity, ethics, and fairness with which group members are treated, and it is significantly related to perceptions of fairness, employee or member satisfaction, commitment, performance, and turnover. This and other forms of justice are important to people in part because they convey social messages concerning inclusion/exclusion, social standing and status, and respect from others. Being treated without justice violates individuals' most fundamental needs for acceptance and belonging. Not surprisingly, violations of personal acceptance and dignity are mentioned far more often than issues such as resource allocation or procedural issues when people talk about experiences with injustice.

While the procedures by which justice is carried out may occur in almost any social context involving two or more people, society is perhaps most well acquainted with the formal procedures of the legal system. Most legal systems are designed to incorporate the same six characteristics central to lay judgments of procedural fairness: (1) consistency (people should receive equivalent outcomes under similar circumstances); (2) bias suppression (prohibitions against "prejudicial" evidence, removal of likely biased jurors, strong advocates for both sides of the question, or prohibitions against conflicts of interest); (3) accuracy (the attempt to gather and present all relevant evidence); (4) correctability (the opportunity to appeal decisions); (5) representativeness (requirements of a representative jury pool, election of lawmakers); (6) and ethicality (strict ethical codes of conduct among decision makers).

Notwithstanding such protections, outcomes of formal legal proceedings can be unjust. Formal procedures for legal decision making may be flawed in ways that systematically bias outcomes. Human actors who must weigh evidence and decide the outcomes can be compromised by subjectivity, cognitive biases, or personal motivations

and conflicts of interest. Justice can sometimes be "bought," as when corporate dollars "buy" the politicians who make the law itself, police or judges are bribed, or one side of a dispute has significantly more power and ability to fund better and more comprehensive representation than the other. Evidence can be hidden, unavailable, or flawed when a murder weapon is destroyed, an eyewitness is mistaken, a witness lies, or a forensic test is contaminated, flawed, or faked.

Moreover, manipulative presentations of individual parties or attorneys can successfully deceive those who must judge as to the existence or meaning of available evidence. Individually and collectively, such mistakes can result in woefully unjust outcomes. Perhaps a greater indictment of the justice system than the many documented errors in outcomes is the fact that these errors are not randomly and fairly distributed. Though flaws inherent to the operation of the justice system can compromise justice for all, social research has shown that some groups are systematically disadvantaged, such as women, racial minorities, the mentally ill, and even the unattractive.

## Conclusion

Though significant disagreement exists between groups and individuals at all levels of social organization concerning what is just versus unjust, what actions should and should not be subject to formal and informal judgment, what procedures are most likely to produce just results, the specific outcomes that can be regarded as just, and even the degree in which justice is attainable (given the flaws inherent to any human justice system), there does seem to be universal agreement that the ideal and pursuit of justice are crucial to the conduct of human affairs. The desire for justice is one that pervades human existence. Unfortunately, ideals of the nature and attainability of these various forms of justice may be out of sync with reality. Some would argue that the very concept of justice is deceptive because, as enacted by less-than-perfect human agents, whether in legal, business, or personal settings, it can go seriously awry.

## Kant, Immanuel

Immanuel Kant was one of the most prolific philosophers and thinkers of the 18th century. Some of his most popular ideas on morals are found in his *Grundlegung zur Metaphysik der Sitten* (1785 *Groundwork of the Metaphysics of Morals*). Kant advocated choosing actions that are “universalisable,” actions that could be adopted by anyone at any time. Kant also advocated an imperative of duty, meaning that one should act as if one’s behaviors could be considered universally adopted principles. Many writers appeal to Kant’s moral philosophy to argue that deception is unacceptable.

Kant outlined a principle of morality that is referred to as the categorical imperative. According to this principle, any action one takes should be considered universally acceptable and should not contradict other universally accepted acts. The categorical imperative generally assumes that humans can arrive at moral principles in an *a priori* fashion. In other words, individuals should act out of a sense of duty to oneself and others as opposed to choosing certain actions based on their anticipated consequences or the promotion of self-interest. Kant’s philosophy is not one that necessarily embraces rules, but it argues in favor of rationalism, which means that morality must override self-interest or the conditions of the situation. In essence, the rule-based ethic implies that

the rule is sometimes nothing more than a guideline. Such a guideline would call for rational consistency, which stipulates that ideas about how to act should be applied unfailingly across contexts.

### Kant’s Formulas

The categorical imperative can be examined through its specific tenets, one of which is the Formula of Universal Law. This formula states that one should never engage in an act unless it can be accepted universally, and if one were to engage in an action, it should be expected that others will engage in it as well. Put another way, if one were to engage in deception, according to universal law, one would have to accept lying as a conventional behavior, and at times one would be deceived by others. By most standards, such a notion is impractical and undesirable; therefore, lying would be deemed unacceptable because it cannot be upheld as a universal law.

Kant uses the example of lying, or a universal law of lying promises (for example, promising to repay a loan when one does not intend to do so), to illustrate this tenet of the categorical imperative. Through his example, Kant argues that most people would not want to be told they were going to be paid back the money they loaned to someone else if this were not to be the case. Therefore, it would be universally immoral for one to make such an empty promise to others.

Another iteration of the categorical imperative is the Formula of the Kingdom of Ends, which some philosophers argue is at the core of Kant's moral viewpoint. This formula stipulates that people should not be treated as a means to an end, but as ends in themselves. An individual should also acknowledge that other people have their own ends. The Kingdom of Ends means that individuals should treat other people based on others' inherent value, not solely on how individuals can use other people to get what they want. To adhere to this formula, individuals would respect that all people should have a choice in the actions they take, and these actions should show a respect for others' agency. This point is not contradictory to the idea that at times individuals treat each other as ends, such as hailing a cab driver to get where they need to go, or asking a colleague to read a writing sample to obtain helpful feedback.

*Immanuel Kant outlined a principle of morality, referred to as the categorical imperative, in which any action that is undertaken by a person should be considered universally acceptable and should not contradict other universally accepted acts.*

However, the categorical imperative stipulates against treating people merely as an end. The people an individual enlists to get the things he or she wants also have their own ends, as well as the agency to decide whether to help the individual get those desired things.

Based on the Kingdom of Ends, being truthful in communication with others is one way to respect the free choice or agency of others. It is through communication that humans find meaning in their circumstances and use reasoning to draw conclusions. Recognizing others' capacities to reason and choose their own actions means that they need accurate facts, perceptions, and information to make informed choices. Being truthful means not hiding one's intentions, while at the same time trying to garner the trust of the other person who is basing some of his or her decisions on the information being given.

When being dishonest, one might compromise others' rational agency by lying to them or giving them false impressions of reality, thus influencing the choices they make. Choices made under false pretenses might be different from those based on veracious and reliable information. According to Kant, lying compromises that communication and the trust among people. Moreover, if individuals accept that others might lie, they have no reason to trust what other people say and acknowledge that they are being treated as a mere end.

Some critics of Kant's viewpoint claim that the categorical imperative and the sense of duty it implies can be unreasonably inflexible and occasionally excessive. For example, adherence to the universal law of honesty might prevent an individual from adhering to another universal law, which might serve a higher purpose in a particular circumstance. To illustrate, a researcher conducting an important experiment on some aspect of human behavior might need to omit certain information about the study's purpose when explaining it to a research participant. Divulging all information about the study up front might unduly influence how the participant performs during the experiment and thus undermine the purpose of the research. One way to rectify this dilemma would be to wait until the conclusion of the experiment and then brief the participant completely on the purpose of the project. Another criticism is that Kant's philosophy overlooks the

pleasure individuals take in treating people as rational agents. People might engage in actions that benefit others out of love or altruism, and not out of a sense of duty.

Kant's moral viewpoint on deception is reflective of his overall stance on an ideal social morality. According to Kant, what helps society function is the adherence to an ethical guideline that stipulates that one engage in an action if and only if that action can be universally accepted and enacted by everyone else living in that society. For reasons articulated in Kant's categorical imperative, and specifically through universal law and the kingdom of ends, deception is never acceptable.

43, he was the youngest person to be elected president. (At 42, Theodore Roosevelt was the youngest person to become president when he assumed office after the assassination of William McKinley.) Despite Kennedy's notable achievements as president, there is a lot of both real and alleged deception regarding his life and death.

#### Deception Regarding Kennedy's Life

In his book *The Dark Side of Camelot* (1997), investigative reporter Seymour M. Hersh provides a negative account of Kennedy's life. Many Americans view Kennedy as a respected and valiant president who brilliantly handled the Cuban Missile Crisis and dealt with Soviet enemies. A lot of the public's perceptions were based on print media and movies about Kennedy that glorified his actions.

Hersh found that the private life of Kennedy belied public perceptions. Kennedy had numerous sexual and extramarital affairs, lied a lot, and used his power for scrupulous and deliberate ends. It was said that Kennedy worked with the Mafia, communist spies, political fixers, and big, money-hungry corporations. Many of the books on Kennedy did not reveal a lot of information on his extramarital affairs, his ill health, and his involvement with notorious people because such information was not as readily available as it is now.

The report of the Senate Select Committee on Assassinations, released in 1975, contains some of the same facts that are found in Hersh's book. Similarly, six of the eight major "secrets" Hersh describes in his opening chapter—Kennedy's health problems, the covert plans for the Cuban Missile Crisis, the plans to relocate Cuban leader Fidel Castro, sexual and extramarital affairs, campaign finance alterations, and recordings in the White House—are also discussed in Richard Reeves's 1993 book *President Kennedy: Profile of Power*.

For a long time, the public had wondered if there was really an extramarital affair between Kennedy and actress Marilyn Monroe or if it was just celebrity gossip. Hersh found a letter written to Kennedy by a lawyer that acknowledged there was an affair. At the same time, Monroe needed to keep her silence about the affair in exchange for receiving a fund in her mother's name.

Hersh also argues that Kennedy was a bigamist. It was said that when Kennedy was an aspiring congressman, he eloped with Durie Malcom, a

## Kennedy, John F.

John F. "Jack" Kennedy was born on May 29, 1917, and assassinated on November 22, 1963. He was the 35th president of the United States. At

very attractive socialite, This marriage was never made public. However, Hersh spoke with Charles Spadling, who knew that the marriage had occurred but was told to eliminate any records of it. Hersh also discovered that Kennedy's brother, Robert F. Kennedy, had stated that Jack had married another woman before marrying Jacqueline "Jackie" Bouvier.

Sources report that Kennedy had been diagnosed with Addison's disease, an incurable illness that affects the adrenal glands. Kennedy and his staff sought to display his youth and vitality, but he was actually deceiving the public about his health. It has been said that if the public knew about his health issues, he might not have been elected president.

Kennedy's own physician, Dr. Janet Travell, declared the president did not have the disease. It was also known that Travell had been giving Kennedy procaine to deal with his back problems. Some who knew Kennedy said that he was addicted to these painkillers. Even though Kennedy had Addison's disease, he tricked others into thinking that his opponent for the presidency, Lyndon B. Johnson, was not strong enough for the office because of his 1955 heart attack.

Hersh also found that Kennedy's brother Robert tried to cover-up his brother's secrets, such as his under-the-table dealings with the Mafia. Robert knew that his brother's Federal Bureau of Investigation (FBI) files would tarnish his impeccable image as president. Hence, after the president was assassinated, Robert tried to destroy all files containing information that would be detrimental to Jack's reputation.

### **Deception Regarding Kennedy's Assassination**

In addition to alleged deception during his life, there have been numerous allegations that the actual facts of Kennedy's assassination have been deliberately hidden from the public. Kennedy's Secret Service officers were ordered to back away from the president while he was riding in a car through the streets of Dallas, Texas, on November 22, 1963. Video images show that the Secret Service men were initially on both sides of the president and were able to protect him from a bullet. However, they were ordered to sit in a car behind the president's car.

The House Select Committee on Assassinations determined that Kennedy's assassination was fact a conspiracy, and not caused by a single gunman. The committee reached this conclusion on the basis of the gunshots heard on taped recordings of police radio reports. Seven shots were on the tapes, but because of budget constraints, only four of the gunshots were analyzed. Based on these results, the committee determined that the shots were too close together to be from one lone gunman. Recordings determined that at least one of the shots was from the grassy knoll area and not from the nearby building from which assassin Lee Harvey Oswald shot the president.

However, the Warren Commission, which also investigated the assassination, concluded that the president was killed by a single shooter. The commission reached its conclusions in secret meetings and then released 26 volumes recounting its findings about Kennedy's death. Some have argued that the volumes were misleading and incomplete. Many of the commission's files were sealed for 50 years.

The Freedom of Information Act, adopted in 1966, allows citizens access to information controlled by the U.S. government. Many researchers tried to gain access in order to understand Kennedy's assassination. Researcher Harold Weisberg asked for FBI analysis of the bullet fragments and Kennedy's clothes. He was denied access, and he believes that the president was not shot by a single bullet.

Director Oliver Stone provided a visual account of the assassination based on many books. In his movie, *JFK* (1991), Stone maintains that Kennedy's death was linked to Lyndon Johnson and New Orleans businessperson Clay Shaw. The movie illustrated the highly controversial conspiracy theory that Kennedy was killed because of his foreign policy in Vietnam and the Soviet Union.

In 1992, President Bill Clinton created a review board to re-evaluate the Kennedy assassination files. The board reviewed over one million pages of records and interviews. It discovered that U.S. Navy photographer Sandra Kay Spencer testified that pictures in the archives that were credited to her were in fact taken by other photographers. Moreover, autopsy photographer John Stringer similarly testified that the archival photos attributed to him were not the ones he took.

The files revealed many accounts of Oswald's vacation to Mexico City, medical evidence that had been tampered with, and Kennedy's planned foreign policy in Vietnam and Cuba. Many of these files are not classified and are open to the public, but there are some that still need to be processed and released. Despite the fact that Kennedy has been dead for some time, there are still many who believe the government was deceptive about the facts of his assassination.

## Knapp, Mark

Mark L. Knapp, an internationally known scholar, is the Jesse H. Jones Centennial Professor Emeritus in Communication and Distinguished Teaching Professor Emeritus in the Department of Communication Studies at the University of Texas at Austin. Knapp earned his Ph.D. from Pennsylvania State University. His research has significantly contributed to the areas of interpersonal and human communication, investigating subjects such as deception through nonverbal communication and relationship development.

As a professor emeritus, Knapp continues to teach courses on lying and deception and

nonverbal communication along with his other activities in research, writing, and consulting. To date, Knapp has published over 10 textbooks in the field of communication and countless journal articles, and he has consulted, taught, and lectured to over 60 business organizations, government agencies, volunteer groups, and educational institutions. He has received numerous awards for teaching excellence and for distinguished scholarship in the communication discipline.

#### Distinguishing Liars From Truth-Tellers

Knapp's research provides crucial insight into several questions surrounding the nature of the act of lying. Layman and researchers alike have sought to identify behaviors that distinguish liars from truth-tellers. According to Knapp and his colleagues, it is difficult to pinpoint precise behaviors of those who are lying; it is easier to identify key emotional and cognitive processes that a liar experiences. The two processes that occur during lying are referred to as "arousal" and "cognitive difficulty."

Nonverbal arousals include the following behaviors: speech errors, a higher pitch in the voice, blinking, and pupil dilation. Verbal arousals from liars include extreme uses of language, defensive retorts, and ill-humored answers. Although liars and truth-tellers may both experience arousal, there is a difference in regard to the second process—cognitive difficulty. Liars have a tendency to experience more hesitancy in their responses, a lack of specific references, and incompatible verbal and nonverbal behaviors.

In his research Knapp discusses two other phenomena that are characteristically associated with those who engage in lying: attempted control and display of an affective state. Attempted control is defined as a rehearsed behavior, indirect responses to direct questions, and a lack of spontaneity when questioned. Affective states typically connected to lying are anxiety, fidgeting, speech stammering, and anger. Anger is one of the most common emotional states related to deception. Liars tend to provide negative and disaffiliative responses; however, there are liars who do express guilt by looking away for an extended period of time and/or placing their hands over their eyes. For those who find pleasure in lying, inappropriate smiles or smirks of contempt may occur at times during questioning.

### Knapp's Staircase

One cannot discuss Knapp without also mentioning his famous and widely studied model, often referred to as Knapp's Staircase. He developed a model of relationship development and deterioration, providing a detailed understanding of the complexity of relationships. The five stages in the process of relationship development from the escalation model: initiating, experimenting, intensifying, integrating, and bonding.

Knapp's model is one that can be used to describe several types of relationships, such as romantic couples, friendships, roommates, coworkers, and family dyads. Not all relationships reach each stage, and stages do not occur in consecutive order; relationships may repeatedly go back and forth between stages.

The first stage of the escalation model is initiating, which can last briefly or an extended amount of time. This is when the dyad focuses on making a positive impression, exchanging greetings and small talk. In this stage nonverbal communication is relied upon to assist with reducing the anxiety associated with knowing little or nothing about the other. Depending on the nature of the encounter, one may choose to provide deceptive or honest information about oneself. If the initial meeting is a successful one, the couple may progress to the next stage, experimenting.

During experimenting the dyad probes for more personal information, determining whether or not they desire to continue the relationship-development process. Probing questions are an attempt to find commonalities, such as hobbies, interests, and similar backgrounds in order to establish a connection.

Couples who make a connection tend to escalate to the third stage of relationship development known as intensifying. The dyad interacts in a less formal, comfortable manner, expressing nonverbally and/or verbally a level of commitment to their relationship. Self-disclosure is an important aspect for the couple to engage in during this stage, revealing one's secrets in hopes that the other will not divulge this private information to anyone.

The next stage, integrating, is when the individuals are an established couple, engaging as one in front of their friends, family, and coworkers. They share a relational identity, using the pronoun

"we" instead of "I" more often. This may or may not lead to the final stage in the escalation model, which is bonding. Bonding is a formal announcement, such as saying the two are "best friends," and marriages, commitment ceremonies, or contractual business agreements.

The other side of the staircase, referred to as the coming-apart stages, consist of differentiating, circumscribing, stagnating, avoiding, and terminating. Differentiating occurs when the dyad seeks more independence, often using the pronoun "I" more than "we," and engaging in activities without the partner.

Circumscribing is the stage in which the couple limits the time they spend together, avoiding conversation by switching topics or outright saying they do not want to talk about the subject. This may lead to the following stage—stagnating. Stagnating occurs when a relationship reaches a point where it is no longer growing; interaction between the couple becomes mundane and/or superficial. If this behavior continues, it inevitably leads to the fourth stage in the staircase, avoiding.

In this stage, deception tends to increase as a relationship breaks down. Dyads may avoid the truth because it is too difficult to face, and replacing it with lies is a way to avoid arguments and confrontations about underlying problem(s) within the relationship. Physically avoiding the other person or omitting parts of one's story are practices that essentially delay the final stage in the staircase, terminating. Terminating signifies that the relationship between the two people is over, whether by mutual agreement, divorce, or death.

In addition to his teaching and scholarship, Knapp has been an editor for the journal *Human Communication Research*, and he served as president of Phi Kappa Phi National Honor Society, National Communication Association, and International Communication Association. Knapp has been the recipient of several awards, and the National Communication Association acknowledges his contributions with its prestigious Mark L. Knapp Award for Career Contributions to the Study of Interpersonal Communication, which is presented annually at the association's convention.

## Korean War

The Korean War was waged from June 1950 until July 1953 between the Republic of Korea (South Korea), backed by the United States, and the Democratic People's Republic of Korea (North Korea), with the support of the People's Republic of China. The conflict resulted from the division of Korea by the Allied forces at the conclusion of World War II. Korea had been ruled by the Japanese empire from 1910 until the conclusion of fighting in the Pacific Theater during World War II in September 1945. At this time, the United States divided the Korean Peninsula at the 38th parallel. The United States occupied the southern part of the country, and the Soviet military operated the north. By the time the Korean War concluded, military forces had used tactics seen in World War I and World War II, including infantry attacks, air bombing, and ultimately trench warfare.

While both sides in the Korean War used tactics of lying and deceit throughout the conflict, these were not as popular as they had been during World War II or would later be during the Vietnam War. Like Operation Quicksilver during World War II, the most brazen use of deceit involved attempts to convince North Korean military officials of a

different time and place for a U.S. invasion than was actually intended. While South Korea and the United States planned to invade at Inchon in September 1950, the United Nations Command devised a campaign using leaflets to attempt to convince North Koreans that the amphibious landing would be happening in Kunsan, an area over 100 miles north of Inchon. The leaflets were dropped from the sky along the southwest coast and warned civilians to not go near the beaches or dock areas. At the same time, a United Nations naval task force and commando landing occurred at Kunsan.

### Deception to Justify U.S. Participation

Looking at the Korean War from a macroperspective, it can be noted that lying and deceit were used in the United States (to some degree) to justify the conflict from its beginning. Much of this information is still hotly contested among scholars and others, but it does demonstrate how presidential administrations can use deceit to encourage support for otherwise unpopular decisions. The deception began when a major lie was used to justify the need for American troops in Korea. The American public was told that the war was spurred by a surprise attack from North Korea, symbolizing a decision by the communists to become increasingly aggressive in efforts to regain control of the Korean Peninsula.

Prior to the beginning of the Korean War, President Harry S. Truman was leaning toward not defending Taiwan against China. Many administration officials, however, were staunchly opposed to Truman's decision, arguing that the strengthening of China could later pose strategic and ideological threats to the United States and the West. John Foster Dulles—perhaps the State Department official most adamantly opposed to communism—worked with General Douglas MacArthur to create the invasion of South Korea by North Korea, which led to the United States choosing to help Taiwan after all. As the Korean War progressed, deceit and lies were used more frequently. MacArthur chose to deflect any attempts at peace accords by staging offensive actions and then exaggerating the estimates of Chinese forces he was fighting against. He went as far as sending forces toward the Yalu River and bombing both Chinese and Russian targets.

To many historians, the Korean War was used as a major tool of deceit in order to help convince Americans to rearm the nation and to fear the potential spread of communism throughout the European and Asian continents. As a result of the Korean War, the draft was reinstituted in the United States and expenditures that had been allocated toward domestic social programs were reapportioned for building the military. Along with the spending priorities, the war led to restrictions on personal liberties, less ability for citizens to criticize government, and less emphasis placed on citizen well-being.

### Claims of Biological Warfare

At another level, the governments of North Korea, the Soviet Union, and the People's Republic of China accused the United States of perpetrating biological warfare as part of U.S. efforts to eradicate communism from the region. In 1951, the communist bloc first began making these allegations, yet these charges were not strongly pursued at the time. They were ultimately publicized in a Report on U.S. Crimes in Korea authored by the International Association of Democratic Lawyers. The reason China, North Korea, and the Soviet Union believed that biological weapons were being used against them was the rapid onset of various diseases among forces on the peninsula.

In January 1952, the Chinese army first received news that there was a smallpox outbreak near Inchon. Then, two months later, disease outbreaks were located in Chorwon, Manchuria, Kimhwa, and Pyongyang. After that, nearly 30 soldiers came down with cholera and the plague, while a number of deceased communist soldiers tested positive for meningitis. While there was no clear evidence, the communist side declared that the Americans must have been behind the spread of disease as part of their war efforts.

By February 1952, the North Koreans began making formal accusations against the United States of dropping insects onto the region that were infected by various diseases meant to harm soldiers and citizens alike. While the United States formally denied any such actions, the accusations were allegedly confirmed by an Australian reporter and several captured U.S. airmen. Likewise, the communists accused the United States of formally testing biological weapons for later use

against citizens in North Korea. Despite the formal allegations and claims of support, the World Health Organization and the International Red Cross both chose to publicly state that no biological weapons were being used.

As would be expected, the Chinese government responded with claims of a severe Western bias within both agencies and asked the World Peace Council to investigate the possible presence of biological weapons. The council's International Scientific Commission for the Facts Concerning Bacterial Warfare in China and Korea found in September 1952 that the United States had been experimenting with biological weapons during the Korean War.

The responses to the World Peace Council's report varied. The U.S. government charged a journalist with sedition for reporting the results of the study. Formally, the U.S. government claimed the allegations were all a hoax and the alleged confessions had been received only after the American airmen had been subject to torture. Australian journalist Wilfred Burchett became a key character in the alleged deceit. Burchett, an alleged agent for the KGB (the Soviet security agency), was accused of concocting the whole story to help garner sympathies for the communist side. However, this claim was refuted on more than one occasion.

Regardless of who actually started the allegations and whether they were true or not, behavior indicates that both the North Koreans and Chinese believed they were true. Mao Zedong, for example, responded to initial concerns by asking Soviet experts for assistance on disease prevention. Likewise, the People's Army mobilized specially trained agents to handle antibiological warfare. Within Korea, antibiological warfare centers were created and housed millions of doses of vaccine and hundreds of thousands of gas masks. Both countries chose to inoculate citizens and set up quarantine stations to prevent the spread of disease. Further, they began citizen awareness campaigns aimed at getting citizens to begin killing any fleas, flies, or mosquitoes they saw in order to prevent the spread of any possible disease.

Historians have pinpointed other potential causes for the disease outbreaks in China and Korea in 1952. For one, the time of year in which

Brigadier General Courtney Whitney (left); Gen. Douglas MacArthur, commander in chief of United Nations Far East Command, (center); and Major General Edward M. Almond (right) observe the shelling of Inchon from the U.S.S. Mt. McKinley in September 1950. The battle represents the most brazen use of deceit in the Korean War, in which Command devised a campaign using leaflets to convince North Koreans that the amphibious landing would happen in Kunsan, more than 100 miles north of the actual planned attack at Inchon.

the events occurred was typically the period in which other epidemics had arisen. Further, past years of warfare in both countries had led to a general demise of the health care system—especially in Korea. Combining a season typically known to produce epidemics with a weakened health infrastructure, it is not particularly surprising that there was widespread disease in the region at the time.

In opposition to the renewed claims, two scholars at the Cold War International History Project released a volume of primary documents gathered from Soviet and Chinese military officials by the Japanese newspaper *Sankei Shimbun*, clearly demonstrating that the North Korean claim was an intentional disinformation campaign aimed at encouraging North Koreans to support the war efforts as much as possible. It was a deceit launched against North Korea's own citizens to foster backing for what could have been an

otherwise unpopular war. Soviet advisors and Chinese commanders invented the scenario, and North Koreans perhaps went as far as to intentionally infect their citizens with disease to help make the claims seem more plausible.

From the perspective of the United States, there have been nothing but unwavering denials since the claims were first made. Following the death of Josef Stalin in 1953, Soviet officials realized that the lies about American biological weapons—which they had helped create and perpetrate—were actually undermining their own credibility. As a result, they stopped pushing the theory (despite never admitting its falsity).

Yet, for every individual with proof that something besides American forces caused the spread of disease, there is a historian still arguing that the United States is to blame. A book released in 1998, *The United States and Biological Warfare: Secrets From the Early Cold War and Korea*, repeatedly

argued that the allegations launched by North Korea, China, and the Soviet Union were true and that Americans were prepared to launch attacks against citizens and soldiers alike. One Australian historian has continued to claim that an American usage of biological weapons was entirely plausible—though admittedly not likely. He points to the confession of Colonel Walker Mahurin, who was associated with a major American biological weapons research facility at Ft. Detrick, as evidence that such an attack was possible. Other historians have pointed to the willingness of North Korean leader Kim Il Sung to believe the possible attacks as evidence that they likely could have occurred. The Chinese government still continues to refute the claim, arguing that there was a serious threat of American biological weapons, and that China had reacted to prevent the epidemic from spreading.

### Conclusion

Ultimately, both sides in the Korean War used lies and deceit to help enhance strategy throughout the conflict. For the Americans, the deceit involved efforts to convince the North Korean, Soviet, and Chinese military leaders that their initial invasion would come at a different location than actually planned. On the opposite side of the coin, communist leaders created a scheme in which the United States would be accused of utilizing biological weapons in an effort to mobilize

opposition and limit support for American forces abroad. In the case of the Korean War, however, perhaps the greatest deceit was in the actual cause for the war and how it fit into the long-term military strategies of the world's clashing social systems at the time.

# L

## Language

The language people use when deceiving others is a topic of increasing interest in the social sciences. Research on language and deception focuses largely on the linguistic cues associated with deceptive speech and on the ways in which speakers utilize language to dissociate themselves from unpleasant topics or events. The most consistent linguistic characteristics associated with deception include increased word count, use of third-person pronouns, and markers of reduced cognitive complexity. Conflicting research findings on linguistic cues associated with deception hinder the ability to generalize findings beyond localized contexts, and emphasize the importance of situational factors when examining linguistic cues associated with deception.

A majority of recent research on language and deception utilizes computer programs to identify the linguistic characteristics of deceitful messages. Of these categories, an increase in word quantity is the most consistent linguistic cue associated with deception.

Language and deception research typically finds that deceivers talk more than truth-tellers. This effect is particularly strong when deceivers are discussing nonverifiable opinions. For example, a person attempting to convince their conversational partner that their favorite food is pizza,

rather than the truthful answer of quesadillas, is likely to expound for a longer period of time on the various reasons why pizza is their favorite food than would a truth-telling counterpart. Deceivers may talk more to manage information flow, to enhance mutuality with conversational partners, and to decrease the suspicions of conversational partners.

### Deciphering Linguistic Clues

Although most studies indicate that deceivers talk more than truth-tellers, empirical findings highlight the importance of task when analyzing linguistic cues associated with deception. When constructing a deception about a verifiable fact, for instance, deceivers offer fewer words than truth-tellers. Similarly, lies of commission associate with increased word count, but lies of omission associate with decreased words counts. Deceptive denials also tend to be shorter than truthful confessions, as deceivers give less detail when their stories contrast a verifiable event. A person lying about a verifiable event, such as their specific whereabouts on a certain night, is more likely to speak in shorter sentences that offer less detail. One way that deceivers offer fewer specific details than truth-tellers is through an increased use of abstract language.

Deceivers tend to use more abstract language in an attempt to conceal the truth from others. High

*Deceivers tend to use more abstract language in an attempt to conceal the truth from others. For example, a teen attempting to deceive her mother with this tactic would answer her question, "Where were you last night?" with something like, "Out with some friends," rather than "Watching the 9:20 movie Getaway at the Southdale 16 Theater with my friend Amanda."*

levels of abstraction in language describe events and actions in broad terms (for example, "fruit," "exercising") and thus obscure the specific details of a story. In contrast, low levels of abstraction in language offer specific details (for example, "navel orange," "Bikram yoga") and provide a more concrete description of the events for the receiver. Thus, a person trying to deceive the receiver of a message tends to speak in abstract generalities that obscure a receiver's specific understanding of the event. In answer to the question, "Where were you last night?" a deceiver is more likely to answer "Out with some friends," rather than "Watching the Mets game at the Eastside Bar and Grill with

my friend John." Deceivers' tendency to speak in abstract language is not without consequence, as the lack of detail and concrete language in deceivers' language often prompts increased questions from their conversational partner, thus inducing a greater number of conversational turns and total word count for deceivers.

Although deceivers tend to speak more than truth-tellers, deceivers' conversational turns are often shorter than truth-telling counterparts. That is, deceivers' total word counts are higher, but individual conversational turns are briefer. Deceivers offer fewer concrete details in their stories, prompting conversational partners to press deceivers for more information, thereby generating a greater number of conversational turns within their interaction.

The finding that deceivers use more words than truth-tellers has been found in both synchronous and asynchronous computer-mediated communication environments. Although existing research results do not differentiate between nonverifiable opinion deceptions (What is your favorite time of day to exercise?) and verifiable fact deceptions (Where were you on Monday?), findings indicate that deceivers talk more in both synchronous and asynchronous environments, albeit for different reasons. Deceivers in synchronous environments often talk more as a result of conversational partners' prompts for more information and detail, while deceivers in asynchronous environments take advantage of the increased time to plan and edit messages afforded by asynchronous communication environments, increasing the detail and subsequent word count of their messages.

Pronoun usage is an area of prominent focus in language and deception research. Findings on pronoun use in deceptive communication are inconsistent and dependent on context. However, a majority of studies indicate that deceivers typically use more third-person pronouns (for example, "she," "him," "they") and fewer first-person pronouns (for example, "I," "me," "my") in their speech. Third-person pronouns direct the focus of the conversation toward other people and away from the deceiver. Similarly, deceivers' reduced usage of first-person pronouns functions to remove the deceiver from the narrative. Deceivers' tendency to use more third-person

pronouns, and fewer first-person pronouns, may indicate a desire for deceivers to psychologically distance themselves from the deception, as they remove themselves from the narrative and focus on other individuals or groups in the story. The tendency for deceivers to psychologically distance themselves may reflect a desire to dissociate themselves from the deception because of feelings of guilt or negative emotion in relation to the deception, or may reflect a lack of authentic personal experience for the deceiver to discuss in relation to the event.

Conversational partners impact the language used by deceivers. Recent findings indicate that both senders and receivers of deceptive communication produce higher word counts than individuals in truthful interactions but use fewer words per conversational turn. The brevity of each conversational turn indicates shorter responses and increased interaction among deceptive senders and receivers.

Research indicates both sender and receiver utterances in deceptive communication are more syntactically complex but introduce less unique information during the conversation, resulting in increased redundancy and repetition of content from previous utterances. The increased syntactic complexity and redundancy of deceivers' language may reflect a tendency for deceivers to stall for time as they formulate deceptions. For instance, a deceiver may repeat their partner's question prior to answering, increasing linguistic redundancy and providing deceivers increased time to think before responding. When asked how they spent their day yesterday, a deceiver may stall for time by including extraneous details to their response that increase the syntactic complexity of their language, albeit without offering information relevant to the question, such as, "What did I do yesterday? Well, it was raining outside, so I stayed in and watched TV." The increased redundancy of deceivers' language may also indicate the desire to focus on simpler, more consistent themes within the conversation, leading to increased repetition of deceivers' responses.

Deceivers illustrate less cognitive complexity in their language than truth-tellers. Because deceivers are forced to keep track of what they have and have not said to avoid contradicting themselves later, deceivers' language often

contains fewer distinction markers, such as exclusive terms (for example, "except," "but," "without") and negations (for example, "no," "never," "not"). Exclusive terms reflect the cognitive complexity of the message as it functions to make distinctions between events, thus offering greater detail to the story. Similarly, deceivers may refrain from using negations in an attempt to avoid using specific language, allowing themselves flexibility in their narrative. At times, however, deceivers may elect to use more negation terms if they lack substantive support for their deceptive statement.

Speakers often use language that is ambiguous, indirect, or imprecise, but not necessarily with deceptive intent. Thus one might describe a neighbor as having a "bun in the oven," even though she has no inclination to do any baking; a politician may fear that public revelations about a plan will hinder his ability to conduct private negotiations and so is vague about its details; a software engineer may explain how a new program works in very general terms because her audience is not familiar with the technical vocabulary suited for a more specific account. In addition, sometimes individuals use language that superficially appears to be evasive but in fact is clear and up front in context. If someone asks, "What happened to my roast beef sandwich?" and someone else responds "Well, your dog looks happy," the semantics of this response may seem off-topic, but the pragmatic implicature it generates (that is, "I think your dog ate the sandwich") addresses the question quite candidly.

### Constructions

Although the examples above are unlikely to be interpreted as misleading, there are occasions when ambiguous or indirect linguistic constructions are attributed to deceptive intent. Unlike outright lies, these constructions can be used without the intent to falsely portray reality but nonetheless could be employed with this goal in mind. There are many "dual purpose" constructions of this sort, but the following are two of the most common:

*Euphemism.* People often use euphemisms to tell it like it isn't. People excuse themselves to "use the restroom" when they have no intention of

resting there, talk of ill acquaintances who eventually “bought the farm” without funds or agricultural experience, and slyly recommend an “adult entertainment” on late-night cable that is hardly mature and even less amusing. Linguists characterize euphemism as a lexical substitution strategy for representationally displacing topics that evoke negative affect (for example, substitution of “use the restroom” for “urinate”). This strategy may serve the ostensibly noble motive of sparing an addressee from communicative discomfort, but it may also serve the communicator’s self-presentational concerns as well. When source identity cues are eliminated from an interaction (for example, one corresponds anonymously with an addressee online), communicators’ use of euphemism has been shown to fall off sharply. Thus, in some circumstances people may be less inclined to use euphemisms to minimize the threat to an addressee’s face than to protect their own.

**Contextomy.** Contextomy refers to the strategic excerpting of words from their original linguistic context in a way that distorts the source’s intentions. One of the most familiar examples of contextomy is the ubiquitous “review blurb” in film advertising. To create these blurbs, studio promoters dissect multiple reviews of a film and then select the most positive comments for use in advertisements. Even when a review is negative overall, studios have few reservations about excerpting it in a way that misrepresents the critic’s opinion. For example, the ad copy for New Line Cinema’s 1995 thriller *Seven* attributed to Owen Gleiberman, a critic for *Entertainment Weekly*, the comment “a small masterpiece.” One might infer from the quote that Gleiberman’s review of the film was positive. In fact, his review was quite tepid. Why then did he use the words “a small masterpiece” in his review? Not to describe the film overall but merely its opening credits: “The credit sequence, with its jumpy frames and near-subliminal flashes of psychoparaphernalia, is a small masterpiece of dementia.” Contextomy can be used to create a false impression of a source’s attitudes in the service of motives as harmless as selling movie tickets or as harmful as character assassination, which is typical of its employment in political advertising.

The influence of situational factors complicates research attempts to assess the linguistic cues that indicate deceptive language. The situational influences on deceptive communication include motivated and unmotivated lies, high-stakes and low-stakes lies, lies of omission and commission, verifiable and nonverifiable deceptions, interactions and monologues, denials and confessions, and literal and metaphorical deceptions. The influence of these situational factors precludes the identification of a consistent set of linguistic behaviors that differentiate truthful and deceptive messages. It remains necessary, then, to consider situation and context when assessing the linguistic cues associated with deceptive communication.

## Conclusion

There are no straightforward answers with regard to linguistic cues associated with deception. The influence of situational factors trumps broad generalizations that connect specific linguistic cues to deceptive communication. Deceivers, in comparison to truth-tellers, typically have higher word counts, use more third-person pronouns, speak in higher levels of abstraction, and illustrate greater redundancy and less cognitive complexity in their language.

## Law and Law Enforcement

The law itself, and the personnel and processes of law enforcement, are among the most interesting and paradoxical contexts for the use and misuse of deception. On one hand, they represent the standards of ethics and morality of society and the rules by which citizens aim to live. In addition, their goals are to enforce these standards among citizens. On the other, the law and law enforcement personnel themselves knowingly violate these standards of ethics and morality.

The law itself specifically condones actions of law enforcement that it specifically forbids other citizens. In turn, law enforcement personnel employ a wide variety of fundamentally deceptive practices to apprehend those they believe to be guilty of crimes; many of these crimes, such as fraud or illegal scams of various sorts, are committed through the use of the very same types of deception used by law enforcement to apprehend the perpetrators (such as misrepresenting crucial facts, or one’s identity). The fate of the accused is then contested by prosecutors and defense attorneys. Whether negotiating a plea agreement,

arguing trial motions to the judge, or presenting the case to juries, the attorneys may selectively present evidence (lying by omission), and knowingly mislead one another, judges, and juries regarding the nature and import of the evidence, all in an effort to achieve the best legal outcome for the state or the defendant.

The pervasive deceptive activities sanctioned by the law itself and entailed in the enforcement of the law raise a number of interesting psychological and ethical issues. Does the end of “justice” justify the means of deceptive or unethical practices? Are these practices unethical when serving the legitimate goals of law enforcement? Do deceptive practices actually serve the goals of truth-finding and justice, or do they unavoidably corrupt and misdirect them? Does use of deception by attorneys and law enforcement undermine public trust? Can police officers who routinely lie and deceive to apprehend criminals draw a bright line of distinction when they testify before juries, or does perjury seem like another justifiable means to an end? Does the process of deceiving others inevitably lead to deceiving oneself? Can attorneys maintain an objective view of the evidence when their goal is to convince others of a biased view, sometimes when they know it to be false (as when a defense attorney knows his client is actually guilty)? In the end, are those who deceive aware of their deceptions, or have they convinced themselves of the truth of their lies?

### Culture of Law Enforcement Officers

The culture of law enforcement officers provides an interesting context for examination of these issues. At one level, their training and culture explicitly endorses lying and deception as necessary means to achieve their goals of apprehending suspects and securing evidence to facilitate their conviction. Training concerning how to perform tasks such as crisis interventions, undercover work, or suspect interrogations not only instructs officers that they can and should lie to suspects and others but also provides specific deceptive strategies along with many concrete examples of individual lies to tell, many described in formal and publicly available training manuals. These formalized deceptive strategies are explicitly sanctioned by law and evolve over time to ensure their continuing acceptability by the courts.

Moreover, distinct sets of implicit rules about lying tend to be instilled and normalized within the law enforcement culture, encouraging and sanctioning particular forms of lying under some circumstances and rewarding the development of deceptive skills and practices. Lying is considered a part of what it takes to “get the job done,” and it is widely believed that one cannot police effectively without well-developed tools of deception. Lying and deception is further encouraged by a culture emphasizing strict control and secrecy and protecting officers from negative consequences for many forms of lying.

In contrast, other forms of lying are discouraged and looked down upon, such as committing perjury or fabricating evidence. Officers are expected—by their own institutions and by the public—to draw a line of distinction between permissible deceptive practices necessary to enforce the law, apprehend suspects, and gather valid evidence and impermissible contamination or fabrication in collection of evidence or presentations of that evidence to others. But it is all too easy for this line to blur and for the impermissible forms of deception to be viewed as just another justifiable means to achieve the goal of convicting a suspect the officer believes to be guilty. Some officers do cross this line and commit illegal forms of deception.

Many common permissible and impermissible practices can be illustrated through consideration of several widely discussed deceptive practices of law enforcement: undercover operations used to gather evidence or apprehend criminal suspects, snitches used to provide incriminating information against suspects, interrogation practices intended to elicit suspects’ confessions, and misleading evidence and testimony offered to secure convictions.

### **Undercover Operations**

Undercover operations represent the most comprehensively deceptive strategies of law enforcement. Particularly in deep undercover operations, those involved not only lie about many specific facts and issues but also must fabricate entire identities and personal histories to gain the confidence of criminal suspects and access to evidence of their criminal activities. These massive deceptions may be carried out over months or years,

and they may entail developing intimate relationships with suspects and even perpetration of criminal activities to maintain the charade.

Arguably, a particular form of undercover operation—the “sting”—could represent the most ethically questionable deceptive law enforcement technique, in that police target a person they believe to be involved in a particular type of criminal activity and pose as either other perpetrators (for example, drug wholesalers) or consumers (for example, drug buyers) to draw the suspect into committing the crime under circumstances where it will be documented. In essence, police officers create opportunities for suspects to participate in crimes for which suspects will then be captured and tried.

Proponents of sting operations point to several advantages of the technique over other methods. First, the sting operation may be cheaper than alternatives such as full-time surveillance (which has the additional disadvantage of posing legal issues regarding privacy). More important, sting operations can serve multiple deterrent functions. Individuals likely to have committed crimes had the operation not been implemented are captured before the crime occurs, and authorities may be able to identify other individuals likely to commit a crime in the near future. Moreover, “word on the street” that police traps may be disguised as criminal opportunities can help deter would-be offenders.

Opponents of sting operations claim that the method simply leads to the manufacturing of crimes and that many who “offended” through such operations may never have considered committing crimes in their absence. Perhaps more damning is the argument that when sting operations prevent the perpetration of the crime, they arguably become exercises of unjustified punishment for unsuspecting victims.

### **Use of Snitches**

A related method to gather evidence involves the use of informants—often low-level offenders—to obtain incriminating information against other suspects in exchange for legal leniency or other benefits to the informants. The informant may be incorporated into undercover operations, where he can perform deceptive functions similar to those of the undercover officers; may attempt

to elicit incriminating information from a suspect while both are in custody; or may simply provide information already (allegedly) known.

The use of such informants (colloquially known as “snitches”) has been the source of controversy among legal circles and the general public. Proponents of the technique claim that offering leniency to low-level offenders is a justifiable moral compromise, affording the legal system effective means of apprehending higher-level criminals.

Conversely, opponents of snitching deals argue that such deals represent an unjustified compromise of law enforcement ethics and justice principles, with undesirable effects outweighing potential benefits. They note that the clandestine and unregulated nature of snitching deals can lead to instances of unanticipated victimization of innocents, corruption, and other ethically questionable outcomes. Incentives offered to snitches can induce them to provide false information, purposely incriminating innocent persons solely to reap the benefits of the deal. Moreover, leniency offered in such deals can encourage criminal activity by allowing informants to escape repercussions of their own criminal activities.

### Interrogation Practices

Interrogation strategies, as practiced by American law enforcement, are arguably second only to undercover operations in deceptiveness. Although interrogators do not deceive at the level of their identity as law enforcement officers, they do so with virtually every other representation made during interrogation. The interrogator feigns good will toward the suspect, indicating that she or he thinks the suspect is a good person caught in a bad situation and stating that she or he would like to help the suspect get the best outcomes. Interrogators promote the illusion that they have the authority to affect whether and what charges are filed against the suspect (which is actually the province of prosecutors).

The interrogator also misrepresents the purpose of the interrogation as an opportunity for the suspect to help himself by “explaining” his side of the story, rather than as an attempt to secure the suspect’s conviction. The interrogator depicts often scant evidence of guilt as overwhelming, often claiming to have evidence such as DNA, fingerprints, failed polygraph tests, or

eyewitnesses that doesn’t actually exist. The overriding deceptive message of the interrogation is that confession is actually in the suspects’ best long-term legal interests, whereas refusal to confess will work against them. While such strategies are effective in eliciting true confessions, they have also been implicated in the elicitation of a growing number of documented false confessions to serious crimes, such as murder and rape.

Modern interrogation strategies were developed not only to deceive the suspects and induce them to confess against self-interest but also to mislead the courts. The importance of full confessions in securing convictions, along with the risk of false confessions raised by coercive interrogation practices, have led to the establishment of laws and regulations in the United States to protect suspects from use of physical violence, overt

*An officer from the Sandwell Police Department discovers a cannabis setup in Wednesbury, West Midlands, United Kingdom, after conducting a warrant at a residence on October 18, 2012. Undercover operations represent the most comprehensively deceptive strategies of law enforcement.*

threats, and false promises of leniency to elicit incriminating admissions. Interrogators acknowledge that suspects are unlikely to confess unless they believe it is in their own best interests.

Since explicit threats and promises regarding the consequences of confession are explicitly forbidden, interrogators have adopted strategies for conveying the incentives for confession without explicitly stating them. The success of these strategies in deceiving the courts is reflected in widespread refusal of the courts to recognize the clarity with which the strategies do convey threats and promises, widespread refusal to suppress confessions elicited through their use, and interrogators' simultaneous success in leading suspects to confess by convincing them it is in their best interest to do so.

### **Fabrication and Misrepresentation of Evidence**

The frustrations and failures of attempts to gather sufficient evidence against suspects inevitably provides the temptation to take shortcuts or to fill in the gaps through fabricating evidence. For example, though deceiving suspects in undercover operations is legally permissible, and arguably ethical, some practices cross the line to intentionally mislead attorneys, judges, and juries who try and judge the suspects. Undercover officers often surreptitiously record suspects in order to document incriminating activities and admissions. If they have difficulty getting sufficiently incriminating statements on tape, the officers may engage in deceptive practices to nevertheless give the appearance that suspects have self-incriminated. For example, the officer may talk about a crime that has taken place or that is being planned as if the suspect is still present when, unknown to the audience, he has actually left the room or walked out of earshot. The silence following the agent's taped statements can be considered "adoptive admissions" of guilt on the part of "silent" suspects.

An agent may talk about picking up some "speakers" (a term dope dealers sometimes use to refer to drugs) with a suspect who understands the term to mean audio speakers. If the suspect agrees to pick them up, observers can later be misled to assume he knew the term referred to drugs. Additional strategies used by undercover agents to artificially convey the notion that targets

have been involved in criminal activities include destroying or tampering with tapes (for example, introducing static to obscure parts of the discussion inconsistent with suspect guilt), interrupting or speaking on behalf of suspects, withholding information from suspects that would clarify what was being talked about (and perhaps lead to suspect denials), and outright scripting suspects so that the target audience ends up hearing, in sum, a recorded full confession in the suspects' own words.

Another of the few contexts in which deception is discouraged involves testifying in court settings. Research suggests, however, that some officers do cross this line. The term *testilying* was coined by New York City police officers to refer to "justified" perjury—ranging from lying about the circumstances surrounding a particular event to outright planting evidence at crime scenes—in a presumed effort to distinguish the practice from inexcusable dishonesty. Many officers who do lie under oath argue that such testilying is justifiable because it serves a greater good. That is, some accept testilying as a way to achieve the goals of justice, even if accomplished through questionable, and perhaps illegitimate, means.

Testilying is believed to be most frequently used to prevent the acquittal of guilty defendants. It has been speculated that one reason officers resort to lying during investigative, pretrial, and trial proceedings is their widespread belief that they are much more skilled at identifying suspects' culpability than judges, juries, and prosecutors. Therefore, it is up to officers themselves to ensure that guilty suspects are not wrongly released, through false testimony if necessary. Other personal reasons why officers sometimes resort to testilying are (1) attempts to cover up their own incompetence or participation in corruption or other illegal activities; (2) monetary gains, such as overtime pay obtained from the extra time it takes to process arrests and testifying in court; and (3) personal or departmental goals to increase conviction rates.

### **Conclusion**

Lying and deception among law officers is legally sanctioned and widely considered to be necessary for effective evidence-gathering, though all such deceptive practices are criticized by some as

unnecessary, ineffective, counterproductive and/or simply unethical—inevitably leading to inaccuracies, injustices, and even corruption. Establishing the legal and ethical boundaries of morally questionable law enforcement practices is a complex endeavor, as it involves weighing goals of efficiency against principles of justice.

their true states may be revealed without their conscious monitoring or control. Although they are sometimes used interchangeably in the literature, a distinction can be made between leakage and more general deception cues. Specifically, leakage refers to behaviors or expressions that reveal a person's true states or feelings, whereas deception cues are those that reveal a person to be lying but give no indication as to the content of the lie. Deception cues are typically independent of context, whereas leakage cues are tied to specific situations. Emotion researchers, verbal and body language analysts, and lie detection experts have attempted to identify, with arguable success, specific and systematic leakage. The topic of leakage and deception has been widely studied in the psychological literature, as well as popularized in the media, over the past few decades.

One well-known event serves as a common example of leakage. In a now infamous 1998 White House press conference, then-president Bill Clinton looked directly at the video camera, shook his finger, and adamantly claimed he, "did not have sexual relations with that woman," a reference to White House intern Monica Lewinsky. Despite mounting evidence to the contrary, many Americans believed Clinton. In polls following his on-air denial, 91 percent of people expressed doubt that he had had an affair. His statement was, of course, later proven false as intimate details of an extended sexual relationship with Lewinsky came to light.

Although the American people were duped, body language and lie detection experts claimed to have easily seen Clinton's true feelings. For instance, they noted that during his press conference, Clinton engaged in several "microshrugs," tiny shoulder movements noticeable only in slow motion, that betrayed the certainty of his words. In addition, the words *that woman* raised alarms, as experts claimed it marked an attempt to psychologically distance himself from his lies. Others noticed an almost imperceptible softening of the volume of Clinton's words at the end of the sentence, indicating a lack of conviction in his statement. Alone, each cue may not have amounted to much; together, they leaked a set of "tells" that experts claim intimated Clinton's affair.

Indicators of deception leak out involuntarily when people lie. For example, a meta-analysis

---

## Leakage

Even when people are highly motivated to deceive others, their behaviors and expressions may betray them. Cues that indicate one's true feelings seep out involuntarily through verbal or nonverbal channels, known as "leakage." During instances of deception, as people try to mask what they really feel or think, information about

of 35 different studies found that deceptive tells include fidgety hand movements, increased blinking and enlarged pupils, frequent speech errors, increased speech hesitations, higher voice pitch, and discrepancies between verbal and nonverbal channels. Such cues to lying, however, are idiosyncratic to the person; for example, some people simply fidget more in everyday life compared to others, even when not attempting to deceive. Nonetheless, as Charles Darwin first suggested and Paul Ekman later popularized, many internal states cannot be completely masked because people are not aware of or voluntarily controlling the behavioral consequences of those states. As a result, even the most well-trained actors, or well-prepped politicians, may leak information about their true thoughts and feelings during deception. One notable exception to this is people with psychopathic disorders; because psychopaths do not typically feel strong genuine emotions, their emotional expressions are easier to mask and leakage is not as likely to occur.

### Five Channels of Leakage

Leakage primarily occurs through five channels—facial expressions, body language, voice, verbal style, and actual verbal statements. The most widely studied and popularly discussed of these channels is facial expressions. For instance, a controversial Canadian court ruling (*R. v N.S.*) required that a Muslim woman remove her *niqab*, a traditional veil covering the face, during her court testimony because facial expressions may provide the jury and cross-examiners with important information. Similarly, airport security officials are trained to scrutinize facial expressions in security screenings. Facial expressions may suggest people's internal states without their awareness or intention.

Facial expressions often leak information through brief involuntary movements, referred to as “microexpressions.” Microexpressions occur for only 1/25 to 1/5 of a second and are too brief for the average person to notice but long enough for well-trained observers to identify. Microexpressions provide valuable insight during high-stakes deception. For instance, researchers studied tens of thousands of frames of television clips depicting individuals pleading for the return of their missing loved ones. About half of the

individuals were later convicted of having murdered the missing persons. That is to say, half of the individuals were explicitly lying when directly appealing with supposed perpetrators to return loved ones. Analysis of facial expressions of “genuine pleaders” and “deceptive pleaders” revealed marked differences. For example, the genuine pleaders' muscles associated with grief, located around their eyebrows and between the chin and the corner of the lips, contracted more so than that of the deceptive pleaders'. In addition, the deceptive pleaders displayed a microexpression of a masked smile when they attempted to appear sad. Experts can identify microexpressions that may leak information about others' true thoughts and feelings when deceiving others.

### Why Leakage Occurs

Researchers suggest the primary reason why leakage occurs during deception is that lying is mentally tiring. During a lie, deceivers actively multitask. For example, they must inhibit their true emotional expressions, wrestle with guilt or worries about being caught in a lie, remember the lies and the facts, and monitor others' reactions. The cognitive juggling that takes place during a lie is mentally exhausting and cognitively taxing. As a result, some information goes unmonitored and leaks out. Research suggests leakage is especially likely to occur when the lie is complicated or the concealed emotions are strong. Because lying taxes limited cognitive resources, unintentional verbal and nonverbal slips may occur without deceivers' awareness.

People are aware that they may give away or leak information during a lie. Moreover, popular media and folk wisdom contribute to people's lay conceptions of the cues that they believe distinguish truth from lie. In a large study of over 63 countries, more than 70 percent of people believed that liars tend to avoid eye contact. People also believe that squirming, stuttering, touching one's face, and telling more detailed stories than is warranted are cues to lying. Because people have ideas about clues that might give away their lies, people often overcompensate during deception. For example, to avoid the appearance that they are not making eye contact, people may instead stare longer than usual. To avoid fidgeting, they may stand or sit in a more rigid manner. Efforts to control

leakage may instead backfire. Overcompensation may actually serve as a signal of deception.

Deception is rampant. On any given day, people hear anywhere from 10 to 200 lies. Strangers lie, on average, three times within the first 10 minutes of meeting each other. During these countless instances of deception, hidden cues to the truth behind the lies may be revealed through verbal and nonverbal leakage, at least for those who know where to look.

## Letters of Recommendation

A letter of recommendation is an official written document that is considered to be an "expert testimony" of an individual's ability to perform a task. Letters of recommendation may also contain information regarding an individual's work ethic, overall character, and accomplishments or professional experiences. The purpose of these letters is

to provide an informed evaluation and possible recommendation to those requesting the letter.

Letters of recommendation are most commonly used for academic selection purposes. Universities and other academic institutions often request multiple letters of recommendation from the professors or academic advisors of students who are applying for admittance. Businesses also utilize letters of recommendations or reference letters to make selection decisions. Organizations, including military branches, will typically request letters of recommendation when making hiring, promotion, and/or tenure decisions. Individuals applying for grants and awards may also need to provide letters of recommendation to ensure that they possess the needed knowledge, skills, and abilities to appropriately utilize a grant or award. In general, when any person or organization is tasked with making an important selection decision, a letter of recommendation may be requested.

Letters of recommendation, like most official documents, are susceptible to unethical activity, such as falsifying information or using information intended to deceive. Letters of recommendation are also susceptible to deception because of their purpose of being a selection tool. Individuals who deceive on letters of recommendation often do so to increase their chances of a favorable outcome, such as acceptance or promotion. Letters of recommendation and standardized reference forms are used because they are able to predict future performance, and applicants who understand this wish to portray the ideal candidate. Applicants who do not feel adequate may be inclined to engage in unethical activity to represent the ideal.

Other motives for using deception in letters may be to cover poor performance or fear of rejection from either the writer of the letter or the establishment making the decision based on the letter. Individuals who engage in social comparison may lie on their letters to make themselves seem more socially desirable. Letters may be forged completely because of the lack of available writers or because the applicants want to gain an edge on the competition and believe they are able to write the letter better than others.

When asked to write a letter of recommendation the writer has two options: to accept or decline the applicant's request. When approached by an

applicant, writers often accept the applicant's request when sometimes the more appropriate option would have been to decline. When writing a letter of recommendation, the writer may intentionally or unintentionally deceive the reader by exaggerating or omitting information. Deception in letters of recommendation is caused by a number of reasons, from legal and ethical concerns to a feeling of obligation to the applicant.

Applicants ask individuals they feel will provide them with the best professional and positive letters of recommendation. The writer often takes this request as an obligation to make the applicant sound exceptional. The pressure of obligation also causes writers to write letters for applicants who they may not know as well as they should in order to provide the readers with an accurate description of the applicant. Discrimination among applicants becomes impossible because every applicant is described by the writer as the best candidate. Research shows high percentages of highly rated applicants and very few average or below-average applicants. Out of 6,854 applicants in one study, only 0.23 percent, or 16 applicants, were found to be below average while 60.27 percent were rated as excellent and 35.94 percent were rated above average. Additionally, research shows that there are more similarities displayed in letters across candidates from one letter writer than there are between candidates with multiple letter writers. In other words, a letter of recommendation is often more of a representation of the writer than of the actual candidate.

### **Detecting and Preventing Deception**

While it may seem nearly impossible for readers to distinguish false information when reading a letter of recommendation about an applicant they do not know, readers can look for warning signs of a deceitful letter. First, readers can look at the relationship between the writer and the applicant. Have the applicant and the writer known each other for a long period of time? If so, then the reader can assume that the writer knows the applicant's weaknesses and strengths, both positive and negative information. If the writer includes only positive information, then the reader may suspect that the letter is inflating the candidate's abilities. Inflation may also occur if the writer does not know the applicant well enough or may

not have many experiences with the applicant and therefore believe they must exaggerate the few characteristics they do know.

Readers should also keep in mind that the letters are written by individuals the applicants trust will provide a strong, positive letter. Therefore, the applicants are going to choose a writer who possesses the least amount of insight into their limitations or weaknesses. Readers should also compare the letters of recommendation with the applicant's resume or curriculum vitae (CV) in order to determine if the information presented from both sources seems compatible. If the resume and CV appear to be in disagreement, then the reader should remain skeptical.

The best way to avoid adding false information in letters of recommendation is for the writers to be able to differentiate when they should and should not provide a letter of recommendation. If the writers know they must fabricate or omit information in order to make the applicant sound desirable to the reader, then the writers should politely decline writing the letter. The writers should also provide criticism and solutions for the applicant's limitations. The reader must also take into consideration that no applicant is perfect. Providing honest praise and criticism is more beneficial to all parties involved than only providing exaggerated positive information.

### **Conclusion**

Letters of recommendation are an important contribution to the decision-making process of an organization or academic institution. It is equally important to understand that these letters are susceptible to fraudulent and unethical activity by all parties involved. Individuals educated in this type of deception will be able to better identify and prevent unethical opportunities and events, while also informing those around them. With an educated staff, these organizations and institutions will be better prepared to examine letters of recommendation and be able to utilize the letters more efficiently.

## Libel and Slander

Libel and slander are two types of defamation claims that involve lies and/or intentional deception. They are both torts (that is, civil wrongs concerning behavior that has caused another harm) that involve defamation, that is, the communication of false information about a person, group, or entity (for example, organization), which results in damages to the victim's reputation. Libel concerns information communicated via a fixed medium, such as newspapers, magazines, and movies. Slander, on the other hand, involves transitory statements, usually oral in nature.

When an individual claims to be the victim of libel or slander, he or she must provide evidence of four elements to be successful. First, the plaintiff must show that the defendant communicated a defamatory message. This means that at least one other person understood the message to have a disparaging meaning that could negatively damage the victim's reputation. Second, the plaintiff must show that he or she can be easily identified as the target of the statement, which was made to a third party without the plaintiff's consent. Situations in which someone overhears a message

conveyed in a manner that should prevent others from hearing it are not considered to be libel or slander. In other words, intent to harm must be a motivating factor, and statements of opinion during private conversations or communications are not subject to a libel or slander label. Also safe from accusations of defamation are distributors of material who have no knowledge of the information they are distributing (for example, mail carriers).

Third, to be defamatory in nature the statement must have been a false statement of fact. Fourth, the plaintiff must show fault, which ranges in restrictiveness depending on whether the plaintiff is a public figure or private citizen. Private citizens have fewer restrictions on building a libel or slander case, as they only need to show that the defendant was negligent. Public figures such as government officials or elected officers bear a higher burden of proof; they must show that the defendant shared information known to be false or with a reckless disregard for whether the information was true or false.

### Common Forms

There are two types of defamation: defamation per se and defamation per quod. Defamation per se is libel or slander that is obvious and completely evident. Composed of four categories, defamation per se includes falsely (1) accusing someone of a crime, (2) accusing someone of having a disease, (3) communicating conclusions about an individual's fitness to conduct his or her business, and (4) implying that an individual has engaged in a serious sexual offense.

Defamation per quod, meaning libel or slander because of circumstance, is not as overt. This type of defamation arises from statements that may seem harmless without considering the circumstances. However, when taken within the context of certain situational factors, the statements become defamatory. Extrinsic evidence is required to prove injurious nature in a defamation per quod suit.

An important distinction between defamation per se and per quod is that, with the former, it is not the plaintiff's responsibility to show damages, because they are readily evident. With the latter, however, the plaintiff must show how the defamation was damaging.

### Defenses Against Defamation Claims

There are a number of defenses available to individuals accused of libel or slander. The first three are called complete defenses because they completely absolve the defendant from any responsibility. The first, the truth defense, involves proving that the defamatory statement was substantially true. This means that even if some of the facts communicated by the defendant are false, if the overall meaning behind the statements is true, then typically defamation has not occurred. Another complete defense is consent. If the defendant can prove that the plaintiff actually consented to the distribution of the statement, then there is no support for the allegations of libel or slander.

The final complete defense is absolute privilege. There are actually two types of privilege defenses, absolute and conditional. Absolute privilege refers to immunity from charges of defamation

based on the defendant's position or status. Absolute privilege applies to judicial proceedings, legislative proceedings, executive proceedings, and statements about a third party to one's spouse. In these situations, officials are not subject to liability for the charges against them, even if their statements were untrue and/or had malicious intent. Conditional privileges, on the other hand, are not based on a person's status or position, but rather arise from the situation during which the statement was made. Unlike absolute privilege, in these cases defendants must prove that they believed the statement was true and that they had reasonable grounds for believing it to be true.

Perhaps the most common defense is claiming that the defamatory statement was stated as opinion rather than fact, although not all jurisdictions recognize the difference between fact and opinion. The success of such a claim typically depends upon whether the person making the statement is in a position to know whether the claim is true or false. Similar to opinion is the defense claiming fair comment on a matter of public interest. In other words, some claim that the press is free to discuss matters of public interest, given that any statements are not made with the intention to harm.

Another line of defense is to claim that the victim of the defamatory statements already had a poor reputation. This defense aims to reduce claims for damages resulting from the statements. A final defense, innocent dissemination, involves claiming that the accused was unaware of the content he or she was disseminating (for example, the post office cannot be held responsible for the contents of letters).

### U.S. Versus International Law

Although there are no federal criminal defamation laws, as previously mentioned, libel and slander in the United States are subject to state criminal defamation laws, although not all states have them. However, even the states without criminal defamation laws have civil laws about defamation. Although only about half of the U.S. states have criminal defamation laws, they are fairly common in other countries, although the specifics of the laws, the punishments for breaking them, and the defenses available to the accused vary. One large disparity between the United States and many European nations regarding defamation is

*Lydia Cacho Ribeiro (left) waits offstage with Kendra Ward (right) before receiving the One Humanity Award at the 2009 PEN Canada event, November 20, 2009. Cacho is a Mexican journalist and human rights activist who was jailed in Cancun in 2005 on libel and slander charges over her 2004 exposé, *Los Demonios del Edén*, which accused prominent businessmen and politicians of running a pedophilia ring. She took the case of her arrest to the Mexican Supreme Court and won in 2007.*

on whom lies the burden of proof. In the United States, it is typically up to the plaintiff to prove that defamation did in fact occur, while in many European countries defamatory statements are assumed to be false unless the defendant can prove them to be true.

### Famous Cases

There are a number of cases that have helped shape current laws regarding libel and slander. One constant battle concerning these cases is deciding where to draw the line between damages caused by defamatory statements and the First Amendment rights to freedom of speech and freedom of the press. In other words, does a plaintiff's claim that a defamatory statement has been made interfere with a defendant's right to freedom of speech and/or freedom of press?

The most oft-cited defamation case is *New York Times v. Sullivan* (1964), as this case was the first to offer direction in terms of who may successfully claim damages due to defamation. In the case, Sullivan, a police official, sued the *New York Times* for printing allegedly false information about his mistreatment of civil rights activists. Although the Alabama state court initially ruled in favor of Sullivan, the U.S. Supreme Court overruled its decision. According to the First Amendment, the freedom to openly debate public officials must be protected, even when the debate includes scathing or offensive comments. To protect this freedom, the court decided that all public officials hoping to collect damages for defamation must prove actual malice (that is, knowing that information is untrue or failing to properly investigate the truthfulness of a statement before making it). In other words, it is up to the public official to prove that the defendant who communicated the information was fully aware that his or her statement was either false or likely false. Because public officials have a higher burden of proof when it comes to proving libel or slander, it is more difficult for them to successfully win their cases than private citizens.

One reason why the courts decided to distinguish between public officials and private citizens in cases of defamation is that public officials willingly place themselves in situations and/or positions inviting close inspection and criticism, thus relinquishing to some degree the complete

protection of their reputation. Private citizens, on the other hand, typically do not wish to be the subject of public scrutiny, and so long as they do not place themselves in situations calling for it, they have the right to protect their reputations. Furthermore, public officials are better able to counteract false statements about them, be it through the media or other connections, whereas private citizens often do not have equal means for doing so. For these reasons, the privacy and reputation of private citizens trumps freedom of speech in most cases.

Considering that the Sullivan ruling applied to public officials, later cases sought to determine who exactly is considered a public official, expanding the definition to include nonelected government employees with control over the conduct of public affairs and candidates for public office. Later, the actual-malice requirement established in *New York Times v. Sullivan* was extended to include public figures outside of the government, such as football coaches and retired U.S. Army generals.

While it is still somewhat unclear what constitutes a public figure, cases such as *Gertz v. Robert Welch, Inc.* (1974) have offered some definition. According to this case, any person who "voluntarily injects himself or is drawn into a particular public controversy" should be considered a public figure for certain issues. This basically means that an individual can become a public figure voluntarily by speaking publicly about a controversial topic, or involuntarily by being accused of committing a high profile crime. Furthermore, an individual may be a public figure for all purposes (that is, those who are familiar to almost everyone) or for limited purposes (that is, someone who becomes a public figure for a limited range of issues).

### How Organizations Can Protect Against Libel

Using the rulings from previous court decisions, organizations can devise methods to protect against libel and slander. For one, organizations should provide training about defamation so employees know their rights and what they are or are not allowed to say about others. Certain situations are protected from libel and slander, provided employees do not cross the boundaries of these situations into unprotected territory. For

instance, when conducting performance appraisals, individuals are allowed to share information about others provided a legitimate need to know the information exists; if a supervisor shares performance ratings or negative information about an employee's conduct to upper management, such a communication cannot be considered defamatory so long as upper management had a justified need to know the information.

Organizations should also exercise caution concerning information posted to the organization's Web site. If information is posted about competing organizations, great care should be taken to present only verified facts. Even if the individual facts themselves are true, if they imply something damaging when taken as a whole, the implied meaning may be cause for a defamation case. Colorful language should be avoided, as its use may result in the communication of unintended meanings by way of misinterpretations. Not only should the organization monitor the statements of its own employees, but it is also the organization's responsibility to review what others external to the organization post on the company Web site, because the organization is liable for these comments as well.

Many organizations readily participate in online social media outlets, such as Facebook, Twitter, LinkedIn, Web sites, forums, and message groups, without taking the proper precautions to ensure that both their reputation, the image of their clients, and the reputation of other similar companies is upheld. If there are any forums or message boards open to the public, a review team should be in place within the organization to frequently review the Web site for potentially defamatory statements made by others and to promptly remove such statements.

To further protect against claims of libel and slander, organizations should be scrupulous in their retention of all records supporting the truth of statements. This may mean keeping records of phone conversations, interviews, and other meetings. An organization should make sure to acknowledge all sides of an issue and thoroughly investigate sources of information to ensure they are reliable and trustworthy. Finally, an organization should consider employing a legal team to review its Web site, literature, and other information it releases to protect against libel and slander.

## Conclusion

Libel and slander continue to be relevant, especially considering increases in ease of communication via technology and the Internet. The definition and boundaries for these two types of defamation continue to evolve as more defamation court decisions are made. It is important that individuals and organizations stay up-to-date on important decisions and work to understand the civil and/or criminal laws of their representative state or country so that they are better able to avoid libelous and slanderous behavior.

## Lie Acceptability

Despite maxims such as "Honesty is the best policy," lying is ubiquitous. Many studies suggest that lying is a communication tool that is adaptive and crucial for social life. People often agree that some lies are acceptable, while others are not.

### Lie Acceptability as Attitude

Because of the evaluative dimensions along which people judge whether a lie is or is not permissible, the acceptability of lying is often defined as one's attitude toward the practice of lying. If a person considers it acceptable to lie (given a specific situation), he or she tends to view the act of lying as one of several options for achieving a social or personal goal. This person is more likely to lie, with less remorse, than another person, who sees the act of lying as unacceptable. The person who views the lie as acceptable will also be less critical and more understanding of another person who lies in that same situation. On the other hand, an individual who considers lying in this situation to be morally and ethically unacceptable would view lying as something to be both avoided and discouraged. It would be unlikely for this individual to lie because he or she would experience guilt by doing so. Likewise, this individual would get upset if others employed the lie against him or her.

### Lie Acceptability as Personality Trait

Another definition views lie acceptability as a trait of an individual's personality: a generalized attitude of an individual toward lying behavior. Measured along a scale, individuals with a high score would see lying as plausible and strategic for social and personal goals. Not only do they lie more frequently, they are also more generous toward others' lies. On the other hand, if they had a low score, they will lie less, experience more guilt, and judge those who lie negatively. Most people fall somewhere between these two extremes.

Of these two definitions, the definition of lie acceptability as one's attitude toward the practice of lying is more common than the definition of lie acceptability as a personality trait.

### How to Study Lie Acceptability

Research has been conducted to learn more about people's attitudes toward lie accessibility. Mainstream studies on the acceptability of lying, especially psychology and communication studies, aim to clarify what determines whether a lie is acceptable or not. In most of these studies, experimenters create scenarios in which participants are asked to evaluate how acceptable or unacceptable it is to lie. The scenarios are manipulated to introduce variations in factors such as the liar's

motivation and the nature of relationships. Analysis is done by comparing scenario variations against participant characteristics such as gender, age, or other demographic groupings.

Some other studies require participants to recall and evaluate actual past episodes; others ask participants to evaluate the acceptability of synonyms for "lie" taken from a dictionary. But scenario-based studies are more common because factors can be controlled more easily.

### Characteristics of a Lie as a Factor for Acceptability

In a simple, moralistic model of lying, the act of misrepresentation is always reprehensible, and a lie becomes more unacceptable as it gets further from the truth. However, outright forms of lying (for example, fabrication) are not necessarily more unacceptable than more subtle forms (for example, misleading statements, distortions). Studies show that the context in which a lie is made has a stronger impact on its acceptability than the lie's form. Some of the conclusions of these studies are as follows:

*Motivation.* The liar's motivation is a powerful determinant of a lie's acceptability. Psychology and communication studies suggest that acceptability is affected by motivation factors, such as the kind of benefit the liar stands to gain, and whether the lie causes harm or good to others. Generally, lies that benefit the liar are less acceptable than those that benefit others. Measured along this dimension, the acceptability of a lie is ranked, in decreasing order, as (1) lies that are beneficial both to the lie-teller and others, (2) lies that benefit the teller but do no harm to others, and (3) lies that benefit the teller while also doing others harm. In addition, lies that are created to avoid losses are generally less acceptable than those made for profit or gain.

*Severity of consequence.* Lying that causes a severe consequence is generally less acceptable than an inconsequential lie. But if the lie benefits the listener, acceptability tends to be high regardless of the situation's importance.

*Relationship between liar and listener.* The closeness of the relationship between the liar and the listener seems to influence the acceptability of a

lie; that is, lies between strangers are more acceptable than lies to a spouse. However, this is not always true; there are cases in which the acceptability of lies between strangers falls somewhere between lying between spouses and lying to a friend. Studies have also found an interaction between relationship and motivation factors.

Characteristics of lie perceivers also influence the acceptance of lying in general, as well as the acceptance specific types of lies. The characteristics of perceiver that are factors for lie acceptability are as follows:

**Culture.** People from different cultures sometimes show different preferences in the acceptability of lies with different motivations. For example, people in China (a collectivist culture) display a different tendency from people in the United States (an individualist culture).

**Personality.** Another important perceiver characteristic that affects the acceptability of lying is personality. There have been no consistent results that show how personalities affect lie acceptance, but subjects with specific personality profiles are more likely to accept certain motivations for lying.

**Other characteristics.** Perspectives also affect the acceptance of lying. In general, people are more generous with themselves than with others when telling the same lie. Some studies show that age and gender have an effect on the acceptance of lies. However, these factors seem to correlate with motivation: only lies made with specific motivations appear to be influenced by age and gender.

## Lie Bias

A lie bias is the tendency to more commonly believe that witness and suspect statements are deceptive rather than truthful. The psychological research literature has repeatedly shown that there is a tendency for the general public to judge others as truthful. However, research shows that police and "professional lie catchers" may be more prone to exhibit a lie bias. This is likely because of the high-suspicion environments in which they work, as offenders also display a lie bias.

There are several explanations for the truth bias, such as that social conventions discourage the challenging of suspected deception and thus allow for poor feedback regarding whether suspected deception did in fact occur. However, the dominant explanation for the truth bias is the availability heuristic: the concept that individuals presume information they hear is truthful, as they are more frequently exposed to truthful information than to lies in their everyday life.

### Police Officers and Lie Bias

If the truth bias is due to the frequency of exposure to truths, it may be expected that in a highly deceptive situation and occupation a lie bias may occur. Therefore, research has examined whether

the frequent exposure to suspects encourages police officers to be more suspicious and thus exhibit a lie bias. There is evidence to show that police officers have a tendency toward more commonly judging statements to be deceptive than truthful. Moreover, when compared with members of the public, police officers more frequently judge statements as deceptive. It appears that increased training and experience among police officers enhances deception detection confidence but has no effect upon actual accuracy.

Thus, the research illustrates that police officers have similarly poor lie detection performance to laypersons. This may be because of the lack of accurate outcome feedback that police officers receive on their deception judgments. If suspects believed to be deceptive are prosecuted, the officer's belief that he or she is good at detecting deception judgment is supported. However, an acquittal can be seen as resulting from legal technicalities and poor juror decision making rather than indicative of poor deception detection ability.

As with members of the public, police officers rely on inaccurate cues to deception, such as decreased eye gaze and increased movements. Lie bias is increased when deception detectors focus solely upon the nonverbal components of suspect interview behavior. Police officers who watched videos of actual suspect interviews were more likely to show a lie bias than officers provided with the accompanying interview audio and those given a combination of visual and audio material. This strongly supports the concept that the cues commonly but mistakenly associated with deception—gaze aversion and fidgeting—are actually more likely to occur in truthful suspects.

Research has shown that participants who were offered a financial reward for good deception detection performance actually performed worse than participants who were not offered a financial incentive. Furthermore, the motivated participants made more false detections (that is, falsely stated that innocent people were deceptive) than the low-motivation individuals. The possible reason for this is that motivated individuals tried harder and so paid more attention to the erroneous nonverbal cues often falsely associated with deception, rather than focusing on the actual content of deceivers' speech. Although conducted with student participants, this research suggests

that the high motivation of the police to identify guilty suspects and thus detect lies may actually impair their deception detection ability.

### **Behavioral Confirmation Bias**

Associated with this is the tendency for pre-existing belief to bias attention to and interpretation of later information, known as the behavioral confirmation bias. The impact of behavioral confirmation bias has been demonstrated to have a negative effect upon the interviewing of police suspects. Officers who believe that their suspect is guilty at the outset of the interview fail to re-evaluate this belief, even when the suspect repeatedly and strenuously denies his or her guilt. This may therefore account for lie bias among police officers.

This behavioral confirmation bias can lead interviewers to fail to acknowledge the innocence of suspects with plausible alibis. This is problematic for two reasons. First, concentrating investigations on an innocent offender removes police focus from tracing the actual offender. Second, the Reid technique advises that investigators ignore the denials from suspects believed to be guilty and instead continue to insist on their guilt. Police insistence on suspects' guilt has been demonstrated to lead to false confessions among vulnerable suspects. However, this supposed validation of the police suspicion of lying may serve to reinforce the lie bias. For these reasons, the United Kingdom does not subscribe to the Reid technique.

Although the lie bias has the potential for serious negative consequences, there is some suggestion that it may be overcome. Lie detection performance feedback can, to some extent, mitigate the impairment caused by a high motivation to detect deception. This effect appears regardless of whether the feedback is accurate or inaccurate, which is useful considering the difficulty in establishing the ground truth in criminal investigations.

### **Offenders and Lie Bias**

The fact that offenders may frequently engage in deception to avoid conviction may make them more sensitive to accurate detection of lies. Moreover, offenders may believe that others lie at the same high frequency as they and thus make them more likely to presume deception than nonoffenders. Finally, the experience of successful and

failed lying in interviews relating to their previous offending could provide offenders with the positive outcome feedback necessary to successfully deceive others. Some support for this suggestion has been found in that prison inmates are less likely than the general public to believe that the inaccurate behaviors of gaze aversion and fidgeting are cues to deception. Moreover, the work of Hartwig and colleagues shows a pronounced lie bias among prison inmates viewing video footage of truthful and deceptive mock eyewitness accounts.

### Conclusion

Whereas the general public consistently shows a truth bias, police and offenders seem to exhibit a lie bias. Research suggests this may be because of greater exposure to lies, more belief in the accuracy of nonverbal cues to deception, and greater involvement in high-suspicion contexts. Although the lie bias has the potential to hinder the proper administration of justice, by reducing motivation to detect deception and encouraging an open-minded approach to suspect interviews, the lie bias may be reduced.

## Lie to Me

A procedural genre crime drama, *Lie to Me* portrays a psychological researcher investigating and solving crimes by using his knowledge of emotion and human expression to become a "human lie detector." Lie detection methods used in this television show are based on the theoretical work of Paul Ekman, and the fictional Lightman Group is loosely modeled on Ekman's training and consulting practice. The program ran on the Fox Network in the United States from 2009 to 2011 (49 episodes) and has been aired internationally in more than 65 countries. The program was generally well received by audiences but has generated controversy among scholars for promoting a single detection perspective in light of unsettled theory.

The principal character of *Lie to Me* is Dr. Cal Lightman (British actor Tim Roth) who, patterned after Ekman, is an expert at detecting deception by reading facial microexpressions and body language. To analyze suspects, Lightman employs the Facial Action Coding System (FACS) developed by Ekman and colleague Wallace Friesen in the 1970s. Lightman's character is brilliant but abrasive and frequently lies to achieve his objectives. Business partner and moral foil Dr. Gillian Foster (actress Kelli Williams) is based on Ekman's former research associate Maureen O'Sullivan. Assistant Eli Loker (actor Brendan Hines) may be based on nonverbal deception researcher Mark Frank, who did postdoctoral work with Ekman. Loker practices "radical honesty," demonstrating that without the social lubricant of white lies individuals often appear insensitive or rude.

In the first episode, Lightman adds Transportation Security Administration (TSA) airport security agent Ria Torres (actress Monica Raymund) to his team. Lightman recognizes her as a natural deception detector and hires her as his protégé. Her background and ability are patterned on characteristics described by Ekman and O'Sullivan in their research on truth wizards.

A typical *Lie to Me* episode includes intersecting plot lines in which the Lightman Group is hired by a law enforcement agency to help solve a murder, investigate threats, catch a thief or spy, find a missing person, or untangle a forensic mystery.

Lightman and his colleagues interview and videotape witnesses and informants in the field or bring them to a laboratory equipped with extensive audio and video recording devices. The dramatic development of an episode often has Lightman using his lie detection skills to determine that someone other than the suspect is lying in order to hide his or her motives or throw off the investigation. The procedural element involves reviewing and analyzing recordings to find the microexpressions, gestures, and other behaviors that will reveal the liar. These reviews are presented in a manner intended to instruct the audience on how to read affective cues. For emphasis, the procedural review of a story character is juxtaposed with media images of familiar politicians, celebrities, or criminals exhibiting the same expressions and behaviors.

### Grounded in Leakage Theory

The science portrayed in *Lie to Me* is grounded in Ekman's leakage theory. Leakage theory holds that the face is a dual system producing involuntary expressions of felt emotion and voluntarily controlled actions that allow people to interfere with felt emotions. The theory posits that most people learn to manage their facial actions using voluntary, deliberate, false expressions; however, involuntary, spontaneous, emotional expressions may leak true feelings despite the liar's attempts to conceal them. According to Ekman, the face can show which emotion is felt, whether multiple emotions are blended, and the strength of the felt emotion. From the earliest years of development, people learn display rules for controlling expressions and concealing true feelings that become ingrained habits operating automatically.

Leakage theory suggests successful deception detection can be achieved by recognizing the complex interactions of voluntary and involuntary expressions as well as vocal cues and other emblematic behaviors, such as a wink or a head nod; noting inconsistencies can also reveal deception. Microexpressions that briefly flash on and off reveal concealed emotion and are considered a primary source of facial leakage. Because of their short duration—less than one-quarter of a second—these clues to deceit are frequently missed. But, consistent with Ekman's research methods, in the *Lie to Me* episodes Lightman and

his colleagues study videotaped images to capture these valuable clues and identify the lies.

The Fox Network employed social media as an integrative means of marketing *Lie to Me*. In addition to offering recent episodes for online viewing and providing cast, crew, and story information, the Fox *Lie to Me* Web site allowed viewers to interact with each other, read a blog by Ekman ("The Truth *Behind Lie to Me*"), test their deception detection abilities online, and contact the Paul Ekman Group for more information. Social media applications create impressions of authenticity and were intended to add credibility to the scientific themes of *Lie to Me*.

### Criticisms of the Show

Criticisms regarding the dramatic portrayal of deception detection in *Lie to Me* relate to the accuracy of how leakage theory is presented. Ekman consulted with the writers and producers of *Lie to Me* and reviewed the scripts, but he has acknowledged that the television program is fictional, and for dramatic effect some of the methods, actor representations, and analyses diverged from his theory. Before or after commercial breaks, viewers also saw billboarded "facts" about lying and deception. These were usually presented without context or citations. Viewers who read the Web site were able to get more information from the Ekman blog, but those who only viewed the program may have been misled regarding the accuracy of information and effectiveness of the techniques presented. An experiment conducted to test the hypothesis that viewers might form misconceptions found that, after watching an episode, *Lie to Me* viewers became less truth biased and more suspicious of people who were telling the truth but no more accurate when looking for lies and deception.

Some deception researchers also question the program's treatment of leakage as the prevailing, accepted theory of detection. At least three other theories offer explanations for how deception is detected. Miron Zuckerman, Bella DePaulo, and Robert Rosenthal's four-factor theory of emotion and nonverbal behavior; David B. Buller and Judee K. Burgoon's interpersonal detection theory; and Timothy R. Levine's truth default theory are considered current alternatives. Each has generated a substantial body of deception detection research

employing different methods than those portrayed in the *Lie to Me* plot lines.

on factors such as the target of the lie, whether the lie is one of commission or omission, the goal for the lie, and the stakes involved in the lie being discovered.

### The Target: Interpersonal and Intrapersonal Lying

Most often when people refer to lies they are talking about untruths or prevarications directed toward another person. This target may be a complete stranger, a casual friend, or a close intimate, but regardless of the exact relationship between the liar and the target, lying in this sense is certainly an interpersonal experience. It is, however, also possible for lying to be an intrapersonal process, one in which the liar is actually lying to himself or herself. Inter- and intrapersonal lying have a great deal in common.

### Lies of Commission and Lies of Omission

When lying is interpersonal, involving another person as the target, both lies of commission and lies of omission can occur. Lies of commission are what people traditionally think of as lies—untruths deliberately told to others with the intent of misleading, misdirecting, or altering the target's perception of reality. A lie of commission requires communication between the liar and the target, a sharing of untrue or distorted information. This type of lying can be verbal, written, or communicated from the liar to the target through a third party, as is often the case with gossip, for example.

Interpersonal lies can also involve withholding of truthful information that the target would need in order to have a more realistic view of his or her own life experience. These are known as lies of omission. In these cases, a lack of communication is essential for the lying process to occur, with the liar choosing to actively withhold information from the target. For example, when a couple is having financial difficulties a common lie of omission occurs when one partner makes an unplanned purchase and deliberately does not tell his or her spouse.

The lines between lies of commission and omission are quite clear from an interpersonal standpoint, but the correlates for those intrapersonal lies, in which the liar and the target are one in the same person, are less obvious and less researched.

## Lies, Types of

An examination of the research on lying suggests that there are many varied approaches to categorizing lies, with no one typology being universally accepted. Most commonly, lies are differentiated

The correlate of lies of omission, when the self is both the liar and the target of the lie, is selective attention and/or directed information search. When people lie to themselves often it is because the reality in which they live is in some way unpalatable. In order to bring their actual reality in line with their desired reality, they pay attention only to information that supports their preferred view of life. For example, people who are having difficulty with their jobs may only acknowledge to themselves the positive and productive things they do at work, while ignoring their failures or weaknesses. In addition, people will often actively seek out information that only supports their preferred worldview. For employees struggling at work, this would entail seeking out feedback only from those coworkers who will say they are doing a good job.

When people cannot ignore information that is in front of them, their next option is to engage in lies of commission directed inwardly toward themselves—a reinterpretation of reality to fit

their desired worldview. These lies of commission often involve the very human tendency to reinterpret events in self-serving, face-saving, or ego-protective ways. For example, having missed an important work-related deadline because of deliberate procrastination, people tell themselves the self-protective lie that the fault for this non-performance actually falls on the employer for setting such an unreasonably short deadline.

### Goals of Lying

In addition to the target of the lie and whether the lie manifested as the giving or withholding of information, the goals of lying can also serve as a way to categorize untruths. There are at least four goals for lying: protecting others, protecting the self, promoting the self, and deliberately hurting others.

*Protecting others.* Ingrained in many societies is the need to be polite. From this social imperative

*When people lie to themselves, it is often because they are dissatisfied with the reality in which they live. Therefore, paying attention only to information that supports their preferred view of life brings their actual reality in line with their desired reality. For example, a worker who is having difficulty with his job may only acknowledge to himself the positive and productive things he does at work while ignoring his failures or weaknesses; he will also seek out feedback only from those coworkers who will say he is doing a good job.*

comes polite lies. These “little lies” are intended to be tactful and are usually known to be untrue by both parties. For example, from a young age, children are taught that the correct answer to the question “How are you?” is “Fine, thank you,” regardless of whether they are in reality feeling fine. In many ways these rhetorical questions are designed to elicit a nonresponse or at least a response that will not require further exploration. Socially acceptable lies such as “That was a great party,” or “Thank you, I love fruitcake,” forestall any further discussion and give the questioners the opportunity to feel positively about themselves, their event, or their gift. In many societies the punishment for not telling these socially sanctioned lies, usually social ostracism, is more harsh than the consequences for those telling the polite lie who are then found out.

Other lies are focused on the belief that the target must be protected, helped, or benefitted by the lie. These are known as benevolent or altruistic lies. Praising a person’s effort to give him or her more confidence, or to tell someone they look great with the intent of making them feel good, would be examples of prosocial lies. Another type of prosocial lie would be lying to someone who intends to harm others. If, for example, a loved one is being abused by their spouse, and someone else knows where the spouse is hiding out, most people with this knowledge would lie to the suspected abuser, saying they don’t know where the victim is staying. As with polite lies, these types of lies would be expected in most societies, and to not lie to protect another would place some of the responsibility for any harm done as a result of an individual telling the truth squarely on the truth-teller’s shoulders.

*Protecting the self.* Not all lies are intended to protect others. Often people lie for the purposes of self-enhancement, or to increase the likelihood of social acceptance. People lie to save face, to avoid embarrassment or disapproval, to avoid conflict with others, and to avert punishment for their own wrongdoing. What each of these situations have in common is a poor choice or unintended negative experience that the person feels compelled to hide or explain in such a way that their positive sense of self is protected. For example, when people are facing a potential conflict

with a friend, one which they realize they have little hope of winning, people often lie to avoid the conflict, either by pretending to go along with the friend’s belief or by conjuring up a plausible, though still untrue, version of the story that will allow them to hold their own in the conflict.

In order to avoid punishment for wrongdoing, people will often resort to lying about what they did (for example, “It wasn’t me who broke it”) or put a more positive spin on why it happened (for example, “It got broken when I was trying to stop the dog from choking on a bone”). Trying to make an intentional wrongdoing appear as though it were an accident or an unexpected by-product of a more positively intentioned act is one of the biggest lies people tell in order to protect their sense of themselves as good people and to avoid the consequences should their actions be found to be deliberate or careless.

*Promoting the self.* Not only can people lie to protect themselves, they also are more than capable of lying in order to promote themselves. This is particularly common in the business world and in closer intimate relationships. Most scholars agree that making a good first impression is a vital part of any successful relationship, be it personal or professional. The key is to make that impression based on the reality of who an individual really is. Many times people will create a false, albeit positive, impression of themselves in order to gain the favor and approval of others.

For example, during the first weeks in a new job, people tend to “put their best foot forward,” taking on projects for which they claim to be prepared to complete but which may in fact be beyond their current scope. The confidence they project may not be tied to any actual capability but serves to give the impression that they were the right hire for the job. Similarly, in online dating advertisements, people tend to lie about their physical appearance, suggesting they are taller or shorter, lighter or heavier, darker or blonder, younger or older than they actually are in real life. All of these lies, which are easily uncovered over time by the target, are designed to create a more positive impression of the self than the individual believes reality promotes.

This type of self-promotional lie is usually tied to an increase in the individual’s positive

self-regard. There is also the potential for self-promotion to result in the acquisition of some form of external benefit for the self, for example, material gain in the form of a raise at work, or relational gain such as a more attractive romantic partner or friend. The dual consequences of improved self-perception and the acquiring of external rewards makes self-promotional lies commonplace in modern society.

*Deliberately hurting others.* Antisocial or malicious lies are the most serious and intentionally hurtful form of lying. These untruths are used by the liar to deliberately hurt the target. While the liar may derive some pleasure from the pain inflicted on the target, the primary goal of this type of lie is to deliberately cause the hurt. Often these malicious lies stem from jealousy or a sense of inadequacy on the part of the liar. For example, someone may tell a wife that her husband has been cheating on her, when indeed he has not. The point of this lie is to cause the wife to become suspicious of her husband's activities, instilling stress in the marriage and potentially leading to the dissolution of the relationship entirely. This need to hurt may stem from dissatisfaction in the liar's own relationships, jealousy over what the target has which the liar does not, or may be used as revenge to right a perceived wrong, such as when a woman's sexual advances have been rebuffed by another woman's faithful husband. Whatever the ultimate reason for the lie, the goal is the same—deliberately causing hurt by sharing untruths.

### The Colors of Lying: The Stakes of Getting Caught

The outcomes of all of these goals have one thing in common: there are stakes involved in getting caught in a lie. Polite lies are often referred to as “white lies,” suggesting they are somewhat innocent and that the stakes involved in telling one and getting caught are relatively minimal. The consequence for someone who lies by saying they like fruitcake when they really don't could actually be positive if discovered because the giver would be less likely to give the offending food as a gift in future.

At the opposite end of the spectrum are the “black lies,” those which, if found out, can have profound and long-lasting negative consequences

for the liar and/or the target. Lies that were designed to be deliberately hurtful, self-protective lies that place blame for negative behaviors on others, and even some prosocial lies can result in negative outcomes ranging from loss of reputation, to loss of job or relationship, or even loss of life. Take, for example, a situation in which a person tells a seemingly prosocial lie suggesting that a family member's death was an accident, when indeed it was suicide. This lie was likely told in order to avoid increasing the pain, suffering, and grief faced by the target, who has just lost a loved one. However, should this individual find out that this was a lie, the “good intentions” of the liar are likely to boomerang, resulting in loss of trust in the relationship, increased grief and suffering, and insult that the liar did not believe the target could emotionally handle the truth. In these situations, there is no winner and good intentions go bad very quickly and sometimes irrevocably.

For the most part, however, the colors of lies more closely resemble shades of gray. Self-promotional lies, some self-protective lies, and many prosocial lies in particular are ambiguous in terms of the consequences of their discovery. The target may understand, or may not. The target may appreciate the need for lie, or may not. The target may initially be angry or disappointed but get over it in time, or may not. These are the lies that can wreak the most havoc in individuals' lives. These lies are the gamble people take when they choose to tell an untruth or to withhold important information from others. The ratio of benefit to potential harm is but one way to decide if, when, and to whom people will lie when they cannot anticipate with any amount of certainty how the target will react if found out.

## Linguistic Cues

Initial research on deception focused on nonverbal cues associated with deceptive speech, like fidgeting that could accompany anxiety. The leakage hypothesis stated that deception is arousing and engenders apprehension, guilt, and anxiety, which are then leaked through nonverbal behavior. However, research since the 1990s has started to focus on linguistic cues to deception and often uses computer applications to analyze texts for certain categories of words that are hypothesized to be related to deception. The underlying assumption is that senders engaging in deception change their language both strategically and nonstrategically compared with senders telling the truth.

Two theories that posit linguistic differences between truthful and false memories are criteria-based content analysis and reality monitoring theory. Criteria-based content analysis theorizes that there are 18 linguistic cues associated with truthfulness. These include a greater amount of logical coherency, more quotes, and more corrections. Reality monitoring theory also examines linguistic differences between truthful memories versus fabricated memories. Fabricated memories are hypothesized to contain less detail, especially sense-based, perceptual, and contextual detail because someone relating a truthful memory would have more access to this information.

Research using computer applications to detect linguistic differences has predominately used two software programs, Linguistic Inquiry Word Count (LIWC) and Coh-Metrix. These computer programs assign words to psychological (that is, negative-emotion words) or semantic (that is, first-person pronouns) categories. LIWC compares every word in the transcript to its internal

dictionary, and it evaluates over 70 different word categories and identifies language indicative of emotional and psychological phenomena and parts of speech. Coh-Metrix also is a natural-language-processing algorithm. Although originally used to examine linguistic features related to the cohesion of a text, research has also applied Coh-Metrix to detect differences between truthful and deceptive text. Coh-Metrix has a larger number of linguistic indices than LIWC (over 700) and integrates more semantic analysis and parts of speech classifiers.

Some linguistic differences may reflect strategic choices deceivers make to reduce the likelihood of detecting their lie. One area in which deceivers may strategically change their language is through the amount of words. Some research has found that deceivers use more words than truth-tellers in order to craft a more believable lie or to control the interaction with the receiver. This has been termed the Pinocchio Effect. However, other research has found that deceivers use fewer words than truth-tellers, possibly to avoid contradicting themselves or to conceal information they do not want to disclose to the receiver.

One moderating variable may be the detectability of the lie. For lies where there is a verifiable fact that the sender could possibly compare with the lie the deceiver may strategically use fewer words to conceal and avoid contradiction with a knowable reality. However, when the receiver is not able to verify the lie (that is, the sender is lying about a nonverifiable opinion), the liar may strategically add more justifications and details to create a plausible story. In addition, some research has found that liars use more causation words (for example, “because”) for similar reasons of construction of a coherent and plausible lie. Other research has found that liars tend to use more words than truth-tellers in computer-mediated communication, where they have more time for strategic lie construction and editing than in face-to-face communication.

### Newman-Pennebaker Model

Other linguistic differences may reflect emotional or cognitive differences between deceivers and truth-tellers that deceivers cannot control or do not know how to control. This research applies the leakage hypothesis to language rather

than nonverbal behavior. For example, function words like pronouns or conjunctions can be difficult for the speaker to control. This research is driven by the Newman-Pennebaker model. This model predicts that liars should use fewer first-person pronouns (for example, “I”) and more third-person pronouns because liars try to psychologically distance themselves from their lies. Psychological distancing may also manifest itself through more use of negations (for example, “never” or “not”) that express a lack of commitment to the lie. Liars should have less complex speech because it is difficult to maintain consistency and create a coherent story when lying, and liars have a higher cognitive load. This reduced complexity of speech should be reflected by the use of fewer exclusion words (for example, “but”). Liars should have more guilt and anxiety because lying conflicts with their self-image. This should be reflected in greater use of negative-emotion words (for example, “sad”), and, finally, liars should use more motion verbs (for example, “go”) because they are concrete and require fewer cognitive resources to retrieve.

Research has found support for this model. For example, researchers examining 500,000 Enron e-mails used the linguistic cues of first-person pronouns and exclusion words to identify deceptive e-mails written by employees of this corporation. Researchers examining deceptive statements made by the George W. Bush administration about invading Iraq found that first-person pronouns, exclusion words, and negative-emotion words could be used to correctly classify a majority of the statements as true or false. Other research has found that linguistic cues are more accurate at distinguishing truth from lies than human coders.

However, other research has found contradictory results or has replicated some linguistic cues to deception but not others. Much of the relationship between deception and linguistic cues may depend on the context of the interaction (for example, synchronous versus asynchronous; face-to-face versus computer-mediated; cultural differences of lie acceptability) and the goals of the deceiver. For example, research examining deceptive online dating profiles found that deceptive profiles contained fewer negative-emotion words than truthful profiles, in contrast to the

predictions of the Newman-Pennebaker model. Within this context, negative-emotion words may strategically be avoided to portray the online dater in a more positive light. Because online dating profiles are asynchronous and editable, deceptive online daters may spend more time strategically editing their profiles, and their speech may be less nonconsciously influenced by emotions. Other research has failed to replicate greater use of negations among liars.

### **Less Complex Speech and Redundancy**

Additional research has examined the less complex speech of liars with shorter and less complex sentences and less lexical and content diversity of words. For example, research with Coh-Metrix found that liars used more concrete words that are more highly associated with other words, are easier to retrieve, and require less cognitive processing. Coh-Metrix results also find that deceivers have more redundancy in their sentences compared with truth-tellers. This is based on latent semantic analysis (LSA) of sentences. Sentences that are redundant with past sentences have similar patterns of words with similar meanings. Deceivers repeat themes and focus on a limited number of semantic focal points. This may be a strategic choice to avoid self-incrimination by limiting the focus to a limited number of topics. It also could be because deceivers are not retrieving information from actual memory and real experiences and, therefore, have fewer remembered details and fewer topics that can be activated. Rather, deceivers are using the context of the conversation for what information can be fabricated, and this leads to greater redundancy within the conversation.

Although the focus of much less research, researchers have also examined linguistic differences between receivers interacting with a lying or truthful sender. This research has found that receivers were more likely to match the linguistic style of deceptive partners than truthful partners but also found that receivers were not able to detect deception at levels above chance.

Research on linguistic cues to deception has predominantly been done on native-English speakers. Whether similar linguistic differences can be found in other languages or cultures is an empirical question for future research. For example, in

other languages, psychological distancing from lies may be manifested by other linguistic cues than pronouns.

like "good" or "right" or "evil," that only evaluate. "Lie" both describes a certain kind of action, and evaluates that action negatively. To characterize an action as a lie, as opposed to characterizing it as a misstatement, or even a falsehood, is not only to single it out as an intentional action but is also to condemn it. This is because a lie has what Sissela Bok has called an "initial negative weight." To accuse someone of lying, to accuse someone of being a liar, is to accuse that person of acting in a way that violates ethical rules. To accuse someone of being a liar is to accuse him or her of wrongdoing.

Such is the negative weight attached to telling lies that it has traditionally been considered the worst form of insult to be accused of being a liar. As Michel de Montaigne said in the following:

Thus I have often considered what could be the source of that custom, which we observe so religiously, of feeling more bitterly offended when reproached with this vice, which is so common among us, than with any other; and that it should be the worst insult that can be given us in words, to reproach us with lying.

Immanuel Kant invoked an article by Richard Steele in issue number 6 of *The Spectator* when he wrote that, "The English *Spectator* maintains that no more insulting reproach could be made to a man than if he is considered a liar." This is presumably the reason why, in the House of Commons in the United Kingdom, no member is allowed to call another member a liar; it is considered unparliamentary language.

In the United States, the U.S. Supreme Court in *Chaplinsky v. New Hampshire* (1942) declared that "insulting or 'fighting words,'" that is, "those that by their very utterance inflict injury or tend to incite an immediate breach of the peace," belong to the "well-defined and narrowly limited classes of speech" that are not protected by the First Amendment's prohibition on the abridgment of free speech. "Fighting words" can be prevented and punished by law, even if they are true. As the court said, "The English language has a number of words and expressions which by general consent are 'fighting words' when said without a disarming smile . . . Such words, as ordinary men know, are likely to cause a fight."

## Lying, Accusations of

As Bernard Williams has pointed out, "lie" is a thick ethical concept, like "coward" or "kind" or "cruel." A thick ethical concept both describes and evaluates. Thick ethical concepts are unlike thin descriptive concepts, such as "walk" or "water," that only describe, and thin evaluative concepts,

The old New Hampshire statute at issue in this Supreme Court case harkened back to 19th-century attempts to ban American gentlemen from engaging in duels, which were brought on by insults to a man's honor, including accusing a man of being a liar. As Joanne B. Freeman has noted:

Coward, liar, rascal, scoundrel, and puppy all demanded an immediate challenge, for they struck at the core elements of manliness and gentility. Any man who uttered them in a dispute was declaring his intention to engage in an affair of honor.

Accusing a man of being a liar, even if it were true, would have provoked a 19th-century gentleman to insist on fighting a duel. Hence, "You're a liar," could be considered fighting words.

Even in present-day negative political campaigns, politicians are loath to accuse each other of being a liar. They prefer to use alternative language, such as accusing their opponents of making "misleading" or "inaccurate" statements. Such language has less negative weight, or uses entirely thin descriptive concepts.

### Accusatory Reluctance

Although accusing someone of being a liar may no longer lead to fighting a duel, and may even no longer be considered fighting words, it remains the case that it is a serious accusation. If the accusation turns out to be false, then the accuser risks a social penalty. As Frederick Schauer and Richard Zeckhauser point out, "it is considered bad form to mistakenly accuse someone of being less than honest." As a result, people refrain from accusing others of being liars, even when such accusations are merited. According to Schauer and Zeckhauser, this fact is known to liars, who take advantage of it:

This is well known to students who ask for extensions on final papers for reasons of computer failure, death of a grandparent, and the like. Although the student knows that the story is false . . . and knows that the teacher knows that the story is likely false, the student also knows that the penalties to the accuser for making a false accusation of dishonesty are high.

Few teachers want to accuse the student of dishonesty only to be presented with a death certificate for the student's deceased grandmother, or the dated repair bill for the computer, or the verified record of a genuine medical emergency. Thus under conditions of uncertainty, even suspicious conditions, we often do not accuse when an accusation is merited.

For many years psychologists have written that the average person's ability to detect lies is poor—just slightly greater than chance. Various explanations have been offered to explain this experimental result. One partial explanation that has been advanced is accusatory reluctance: people are reluctant to accuse other people of being liars. According to Maureen O'Sullivan, although subjects in experiments with lie detection are quite willing to rate the people they view in videos as being uncomfortable (which is correlated with lying), or as thinking harder (which is also correlated with lying), both of which are thin descriptive concepts, they resist accusing them of being liars: "Thus observers have no trouble labeling liars as less comfortable or as thinking harder than truth-tellers, but when it comes to applying the term *liar*, observers show a surprising amount of accusatory reluctance."

One explanation for accusatory reluctance is that the rules of social courtesy and the parameters of social life restrict people from accusing others of lying. Erving Goffman maintained that people have been reared to be polite in their social interactions, and this can extend to refraining from accusing each other of being liars.

### Ekman on Accusations of Lying

Paul Ekman was one of the first psychologists to write about why people are generally unable to accurately judge from other people's demeanor whether or not they are lying, granted that there is no human equivalent of a "Pinocchio response"—a behavioral sign or constellation of signs that, across every person, in all situations, indicates that someone is lying. Even if, as Ekman contends, evolutionary history has not prepared people to be sensitive to the behavioral clues relevant to lying, this still does not explain why people might not learn this detection skill during their own lifetimes. He offers three possible explanations.

*Serena Williams, in her match against Caroline Garcia of France in the 2013 French Open, appears calm before the line judge, May 29, 2013. However, in a U.S. Open semifinal match against Kim Clijsters on September 12, 2009, she launched into a now-famous profane outburst as she accused a line judge of lying over a foot fault. The negative weight attached to lying has earned its standing as one of the worst forms of insult. In the 19th century, accusations of lying would even be grounds for initiating a duel.*

Ekman's first possible explanation is that parents socialize their children into not accusing their parents of being liars and, more generally, teach their children not to identify lies:

Their privacy may often require that they mislead their children about just what they are doing, when they are doing it, and why they are doing it. While sexual activity is one obvious focus of such lies, there might well be other activities that parents want to conceal from their children.

Ekman's second possible explanation is that in general, accusing people of being liars makes life more unpleasant for the accuser and can undermine the possibility of establishing close relationships:

. . . we generally prefer not to catch liars, because a trusting rather than a suspicious

stance enriches life, despite the possible costs. To always doubt, to make false accusations, is not only unpleasant for the doubter, but undermines much chance of establishing intimacy in mating, friendships, or ongoing work relationships. One cannot afford to disbelieve one's friend, child, or spouse when he or she is actually telling the truth, and so one errs on the side of believing the liar. Trusting others is not only required, but it makes life easier to live. What matter if the cost is not detecting some who take advantage of that trust?—and one might not even need to know about it. Only the paranoid who forgoes such peace of mind—and those whose lives are actually at some risk if they are not constantly alert to betrayal.

If one comes to believe that someone in one's social circle is a liar, then, Ekman argues, one's likely response is to cease interacting with that person, rather than to accuse that person of

being a liar and determine if one is correct: “If you were to decide that your friend had lied to you, how would you determine if you were correct? Most often, I expect, you would simply stop seeing the friend.”

This reluctance to accuse someone of lying when one has a suspicion that he or she is lying means that there are many missed opportunities for people to learn the truth about whether or not they have been lied to and to develop their skills at detecting lies: Ekman maintains, “The failure to definitively check your judgment against an independent criterion of truthfulness is probably quite common and responsible for people generally not learning from mistaken judgments.”

### Collusion With Liars

A third possible explanation is that people may be reluctant to accuse others of being liars because of collusion with the liar. This collusion, however, can take at least two forms: current collusion with the liar and retrospective collusion with the liar.

Accusing others of lying while being lied to could bring the lying to an end, which may not be desired. In some cases, people wish to be lied to, for their own benefit. For example, those who invested their money in Bernard L. Madoff Investment Securities—before Madoff finally admitted that, “It’s all just one big lie”—never accused him of lying, despite the fact that he delivered such high returns in good and bad markets, because this might bring their own profits to an end.

Accusing another of lying, after having been deceived, could also lead to being exposed as a dupe who should have known better. Sociologist Brooke Harrington surveyed investors who lost half or more of their savings because of financial deception by large companies, such as Enron, in the 1990s. She was surprised to find that many investors did not accuse these companies of deceiving them but rather considered themselves as participants in the deception, even though they were in no way involved with the companies’ fraudulent schemes: “Many spoke of a sense of complicity in the decline of the bull market, as though their actions contributed to falsified accounting statements or to corrupt auditing and governance practices.”

This retroactive collusion with liars is a phenomenon Goffman has described as adaptation

to failure. For the victim of a con, the loss of money is less distressing than the loss of identity as a competent, intelligent individual who could see through the lie. Refusing to accuse another of having lied to one is a way of refusing to face up to the reality of having been duped, with its attendant humiliation.

## Lying, Costs of

Lying is an expensive act. Planning, performing, and maintaining a lie is extremely tiring. Moreover, when the lie is detected, it subjects the liar to punishment, disrepute, or awkwardness. Thus, studying how much lying costs provides insights into how to politically, economically, or personally deal with this tempting but socially inappropriate act. Studies on cognitively expensive lying are a new type of lie detection tool; studies on emotionally expensive lying shed light on the nature of people who do not lie enough.

### Cost of Lying as Cognitive Load

Many psychology studies suggest that lying requires greater mental effort than telling the truth. Compared with producing truthful speech, deceptive speech generates characteristic behavioral cues that indicate the increased cognitive effort: longer response latencies; more speech hesitations; pupil dilations; less hand, facial, and eye movements; gaze aversion; and higher skin conductance levels. The increased cognitive effort is mainly relevant to two components of the lie-production process.

The first component of the lie production process is to construct a false message. The liar must handle automatically activated social-cognitive and contextual knowledge. They must suppress harmful (but true) elements of the message, while producing plausible (though false) alternative elements, so that their false message aligns with the remaining truthful elements as well as the target's knowledge.

The second component of the process is to monitor one's outward behavior and the target's reaction, to assess whether he or she is successful in the lie. The liar can then adjust his behavior based on his assessment, avoiding the target's suspicion.

These two components of lie production are deeply relevant to the executive functions—the effortful, deliberative, and conscious cognitive functions, such as attention, metacognition, working memory, and inhibition. These same functions play a central role in planning, decision making, problem solving and other complex cognitive tasks.

Some recent studies suggest that making use of the cognitive load of lying can help in the development of lie detection tools. Albert Vrij and his

colleagues conducted an experiment in which participants reported their stories in reverse chronological order. Liars showed less plausible and less detailed responses than truth-tellers. In another experiment, Jeff Walczyk and his colleagues tracked eye movements and other cognitive cues of participants. Liars showed longer response time, less consistent response, and fewer eye movements.

These studies demonstrate that when additional cognitive load is imposed (for example, by reverse-chronological-order report or by eye-gazing), liars get too tired to maintain their “truthful” appearance and give away behavioral cues, such as less plausible and less detailed reports, longer response time, or fewer eye movements. These behaviors are exclusive to people who are lying; truth-tellers do not exhibit these behaviors because they are not busy with the extra cognitive effort involved in lying.

However, other researchers suggest that telling the truth can be cognitively expensive too. In Steven McCornack's information manipulation theory 2, the information (whether truthful or false) that efficiently resolves the discrepancy between current-state and desired end-state is activated more and is more easily fed to the speech realization system. In fact, if the truth doesn't resolve the discrepancy, the truthful information would be rather suppressed and would require a greater cognitive load to realize into speech. In other words, it is easier to lie in such a situation.

### Cost of Lying as Disincentives and Countermotives

Lying is also studied in the field of behavioral economics. For example, Gary Becker has used his Simple Model of Rational Crime (SMORC) to study the impact of rational choice on unethical behavior. Based on his model, people commit crimes on the basis of cost-benefit calculation: they simply compare the possible positive outcomes with the possible negative outcomes of committing a crime. In the context of lying, liars can quickly estimate how much money they can gain from lying, what punishment they will receive if caught, and how likely it is that they will be caught. If total benefits exceed the total costs, they will lie; if being honest is more beneficial, they will tell the truth.

The SMORC presents a straightforward solution to decreasing dishonesty in society: Society should simply raise the cost of lying in terms of disincentives, such as setting expensive fines for lying, or should increase the probability of detection by monitoring people's words and behavior in order to detect their lying. When the cost of lying is greater than the benefit, in most situations people will remain honest.

However, there is a greater variety of lying costs than just the punishment and risk detection suggested by SMORC. Morality violation, for example, can be seen as another cost of lying. Taking the extreme position of Immanuel Kant, who believed that lies were prohibited under all circumstances (even if faced with a would-be murderer), the cost of morality violation incurred by lying would be infinite. However, morality is too vague a construct to measure as a cost, and several studies have examined more quantifiable costs of lying.

### **Additional Costs of Lying**

Beyond Becker's SMORC, several researchers have investigated the psychological costs of lying.

*Others' loss.* Behavioral researcher Uri Gneezy investigated how people behaved toward monetary incentives when there were no economic costs to lying, no risk of detection, and no punishment for detection. He used a sender-receiver game, in which the sender knows the payoff for two alternative options, and the receiver has to select one of the options. One option paid the sender more than the receiver, while the other paid the receiver more than the sender. The sender could communicate with the receiver before he made a decision, that is, told the receiver that option A paid the receiver more, when in fact it was option B. There is no risk of being caught for the sender, because even after payment is made to these two players, the receiver doesn't know about the payoff for the unselected option.

The SMORC model, which assumes that all actors are rational, predicts that all the senders would tell the receiver a lie. However, Gneezy found that not all the senders lied. More significantly, when faced with a large decrease in the receiver's payoff, less than 20 percent of the senders lied. This result suggests that the target's loss

can be considered a type of cost that discourages potential liars.

*Lying aversion.* Another study by Gneezy and researcher Sanjiv Erat suggested that the act of lying itself incurs a cost. This research project used a modified version of the sender-receiver game in which the option was determined by the receiver's guess about the outcome of rolled dice, and the sender knew the outcome as well as the payoffs for the alternative options. When the receiver guessed the right number of the dice roll, this option did not benefit either of the players. The sender could communicate the actual number of the dice roll to the receiver, but in order to let the receiver choose the option that would benefit both sender and receiver, the sender needed to tell the receiver the wrong number. If a sender chose not to lie to the receiver, it indicated a counter-acting tendency against telling a lie, even without the economic or social costs obtained from the receiver's loss. The result was that 35 percent of the senders did not lie, which means that the act of lying itself incurs a cost for some people.

*Size of lying.* Researcher Tobias Lundquist and colleagues suggested additional characteristics of lying aversion by designing a game similar to the sender-receiver game. They observed that the likelihood of the sender lying decreased as the lie got further from the truth.

Researcher Dan Ariely and colleagues investigated the size of lying in a task achievement report. Participants were asked to solve 20 math problems within five minutes and then report their achievements. By comparing the students' reports with the actual achievements obtain from secretly collected answer sheets, researchers calculated the size of the students' cheating. They found that the students on average reported solving two more problems than they actually performed. This number was stable even when the experimenters raised the payment for solving each problem. The results indicated that people did not like to tell lies that were exaggerated beyond their comfort zone, even when a bigger lie had a larger monetary incentive.

Ariely concluded that liars kept their lies within a range in which they could keep a reasonably honest self-image. In other words, the extent

of lying was neither economically oriented nor socially referenced, but self-referenced.

*Distance from commitment for lying.* In a variation of his experiment, Ariely compared two methods of participant reporting. In one method, participants reported with the template, “I solved X tasks. Please give me X dollars.” In the other, participants followed another template, “I solved X tasks. Please give me X tokens.” Even though the tokens were immediately exchanged for cash, the token option resulted in twice as much lying as the cash option. In other words, when the payment was one step removed from receiving actual money, the amount of lying increased. This finding suggests that as the distance from commitment for lying decreases, the cost of lying increases, because people can still lie and feel good about themselves.

These study results provide many hints for creating easier and less rigorous solutions to regulate dishonesty in society rather than increasing punishment or monitoring. Considering the psychological costs of lying, people cheat less than the SMORC suggests—and this is good news.

## Lying, Difficulty of

A truism within folklore and lay belief is that lying is harder than truth-telling. Parents and pastors alike entreat their children and followers to “be honest,” in part because “it’s easier to just tell the truth.” Correspondingly, literary, film, and online depictions of lying routinely emphasize the difficulty of its production: liars are characterized as distracted, nervous, and occasionally overwhelmed by the cognitive task of being duplicitous.

Deception scholars are similarly enamored with this belief. Lying is considered to evoke “greater cognitive load” (i.e., more mental effort) than truth-telling, for several reasons. First, the production process associated with lying is presumed to be very different from truth-telling. Lies have to be “made up from scratch” or “manufactured,” whereas truth is thought to be streamed effortlessly from memory to mouth. Second, scholars emphasize that liars need to “be believable,”

“maintain logical consistency” in their messages, and “remember their lies,” whereas these considerations are thought to be absent (or effortless) for truth-tellers. Third, liars are thought to be preoccupied with the possibility of detection; hence, constant vigilance and effort is needed as they strategically adapt their behaviors in order to be believed.

### **Are Nonverbal Cues and Cognitive Load Really Indicative of Deception?**

Scholarly belief in the difficulty of lying is foundational to past and current theoretical models and research programs of deception detection. Because lying is believed to evoke greater cognitive load, scholars have long suggested using load-related behavioral cues as indicators of deception. For instance, increases in cognitive load often result in longer response latencies (i.e., delays before responding to questions), longer pauses while speaking, increases in speech errors, and increases in the number of filled pauses (including “umm” and “ah”). Because lying generates greater cognitive load than truth-telling, scholars presume that these behavioral indicators should accurately distinguish liars from truth-tellers, thus allowing for detection.

Empirical research, however, has failed to document that nonverbal behaviors indicative of cognitive load differentiate honest and deceptive communication. In fact, behavioral signatures relevant to cognitive difficulty for truth-tellers and liars appear to be quite similar; therefore, such signatures are not useful for lie detection.

Given that behavioral cues signaling cognitive load do not reliably differentiate truths and lies, some researchers now suggest that increasing load beyond what would be “normal” for liars and truth-tellers constitutes an efficacious way of detecting deception. The reasoning is twofold: if lying can be made too difficult, then people will either (1) just be honest or (2) give themselves away. Strategies used by these researchers for increasing the cognitive load of liars include asking unexpected questions and asking people to provide information in reverse chronological order.

A small subset of scholars, however, has begun to challenge the orthodoxy that lying is intrinsically harder than truth-telling. Bella DePaulo's work in the late 1990s was seminal in this

regard. She had respondents record in a diary the everyday lies they told in conversations. Contrary to lies being planned, arousing, involving, and effortful, she found that the average lie was unplanned, casual, and (importantly) involved minimal cognitive effort. Subsequent to this work, Steven McCornack offered a scathing indictment of what he called the “cognitive load hypothesis” (i.e., the argument that lying always evokes high cognitive load), noting that lying within many contexts involves cognitive efficiency advantages over truth-telling.

More recently, McCornack, in his information manipulation theory 2, identifies the cognitive mechanisms underlying the production of lying versus truth-telling and concludes that the two forms of discourse borrow on largely the same speech-production processes. That is, during both lying and truth-telling, speakers stream information straight from working and long-term memory to speech production, guided by the simple imperative, “what's the most efficient way to deal with this situation?” Because lying and truth-telling involve similar production processes, no differences in load between them should be observable, in general. Data supportive of McCornack's arguments have been found in cognitive neuroscience. Professor Giorgio Ganis recently reviewed findings from several dozen studies involving the brain scans of liars and truth-tellers and found no consistent, discernible differences in the brain functioning of the two groups.

Critics of the cognitive load hypothesis do admit, however, that lying should be more taxing than truth-telling when three factors are present: the truthful information one possesses is contextually unproblematic, the truthful information is easily accessible within memory (i.e., involves data that recently were uploaded to working memory), and any false information that might be used to construct the lie is difficult to retrieve from long-term memory. However, there is a “catch” to this particular intersection of antecedents: in situations such as this, people do not lie. That is, when the truth isn't difficult to disclose (because it's easily accessible to the conscious mind and is contextually palatable), people disclose it.

When do people lie? When they judge the truthful information as being so problematic that it can't be disclosed. And why do they lie?

Because it is less load intensive to construct a message based on situationally appropriate, false information than trying to package the problematic, truthful information into face-maintaining linguistic form.

### The Importance of Context and Strategic Evidence

The fact that cognitive load is largely determined by context and not by the act of lying per se is borne out by the research of communication scholar Kelly Morrison. She had respondents imagine that they had contracted a sexually transmitted infection through an act of infidelity. She then tasked them with generating messages to romantic partners encouraging them to get tested. Subjects who lied in their messages reported substantially less load than those who told the truth. Morrison also asked respondents to identify what would have been the “easiest thing to say.” Consistently, people reported lying as the “easiest” option.

Although lying isn’t intrinsically more difficult than truth-telling for most people, certain persons find lying challenging. In fact, Timothy R. Levine has observed that a small percentage of the population finds it almost impossible to credibly lie; he has dubbed these lie-challenged individuals “transparent liars.” Transparent liars, when they attempt deception, consistently give themselves away by blushing uncontrollably, giggling, or displaying other indicators that make their lie obvious to almost anyone observing. These people typically are aware of their inability to lie; consequently, they are less practiced at lying than most people, worry more about giving themselves away, and tend not to lie in general.

It also appears that skilled interrogators can make lying more difficult than truth-telling through the kinds of questions they ask. Skilled interrogators pay careful attention to what is said and seek to trap liars in their lies by careful attention to the consistency of statements and the strategic use of evidence, which involves initially withholding factual knowledge and then confronting a liar with that evidence only after the liar has lied. Information might also be fact checked later. Effectively lying in situations where there is careful scrutiny to everything said, prior and subsequent fact checking, and skilled questioning

is substantially more difficult than either honest communication or everyday lies.

## Lying, Intentionality of

Most people agree that lying is intentional, that is, performed with a specific purpose of deceiving. Brain and nonverbal studies suggest that telling the truth is an automatic response and that engaging in lying is deliberate and requires higher brain

processes, including inhibiting the truth response, constructing new information, and taking perspective of the other person's mental states. There is some evidence, however, that lying can occur without intention. Young children lie before they understand that by expressing false statements, they can create false beliefs in another person's mind. Furthermore, research has showed that when people do not have the capacity to engage in deliberate thought, lying still occurs when the act of lying serves the self. So, lying often occurs intentionally, but some lies may not be expressed with the intention to create a false belief in another person's mind.

### Intentional Lying

Most definitions of lying provided by deception experts and dictionaries include the information that lying occurs intentionally, that is, lying is deliberately making an untruthful statement to deceive. The general conception is that truth-telling is the automatic response and that people only lie when they have a reason to do so, for instance, when they want to present themselves more favorably to attain a goal or when they want to avoid hurting another person.

When in a situation in which lying might be more beneficial than truth-telling, people often deliberately think about what is the best response given the circumstances. Neuroimaging and event-related-potential studies confirm this idea by showing that when people lie, there is more activity in brain areas involved in executive functioning. This suggests that people engage in processes that regulate, control, and manage cognitive processing, like inhibition, planning, working memory, and initiation and monitoring of actions. So enhanced cognitive processing involved in lying is due to: (1) deliberate thinking about whether to lie or tell the truth, and (2) cognitive processing when telling the lie (for instance, taking perspective of the mental states of the people being lied to), which occurs regardless of whether the lie is intentional.

Studies on nonverbal aspects of lying are in line with the idea that the truth is an automatic response that is inhibited when lying. These studies showed that liars are more likely to speak slowly, have more speech disturbances, and take longer speech pauses than truth-tellers. Liars also show

fewer body movements. Finally, people respond faster when their response is truthful compared with a lie. Research on ethical decision making also suggests that people intuitively respond ethically but are more likely to lie when they engage in deliberate thinking.

Thus, there is ample evidence suggesting that lying occurs intentionally. When an untruthful statement is made without intention to deceive, this is often not regarded as real lying, as is the case when someone lets another person know their statement is false by joking or teasing. A person can also express an untruthful statement but not know that the statement is false if he or she was not provided with accurate information or if a memory error occurred.

*At the age of 2, children are able to grasp the distinction between reality and a false belief and will therefore engage in denial when asked if they did something naughty (when in fact they did). It is still unclear, however, whether lying at the age of 2 or 3 is true deception or just wordplay or wish fulfillment.*

### Unintentional Lying

There are a few instances, however, in which an untruthful statement is regarded as a lie and does not seem to be expressed with the intention to create a false belief in another. This occurs in young children, in people who have a chronic self-serving goal, and in pathological liars.

Young children start to lie even before they understand the intentionality of lying, which suggests that lying can occur unintentionally. At the age of 2, children engage in denial when asked if they did something bad, when in fact they did. They are able to make a false statement at the age of 2 because they are able to grasp the distinction between reality and a false belief. Children at this age, however, do not yet understand that their own thoughts can be different from others and, thus, they do not understand that they can express a statement that they know is false and know another person will regard as true.

It is still unclear whether lying at the age of 2 or 3 is true deception or just wordplay or wish fulfillment. It is possible that when children use denial to avoid being punished, they are engaging in a rudimentary form of intentional lying to protect the self: children want to protect the self from punishment, which may occur without a real intention to create a false belief in another person's mind. Between ages 10 and 12, children are fully able to grasp the intention of the lie.

In a similar way, adults seem to lie without deliberating about the consequences this lie brings to another person. Research shows that people have an automatic (that is, without deliberate thought) tendency to act upon their self-interest, even if this means they have to lie. This implies that people's automatic tendency is to lie if engaging in lying is beneficial for the self. People who are depleted or under time pressure, and thus are not able to deliberate on what to do and why, are more likely to lie when this serves the self. This suggests that lying can occur without deliberate thought. Responding automatically implies not deliberately thinking about the purpose for reacting the way they do (that is, unintentionally). Although in this case people do not deliberately think about whether and why they should lie, people can have a chronic goal which leads them to lie automatically, for instance, when people have an automatic goal of serving the self.

Finally, another example in which lying seems to occur unintentionally is when a person is a pathological liar. Pathological liars lie with the purpose of lying, not necessarily intended to create a false belief in another person. Their lie response is an automatic response and is made without deliberately thinking about the consequences of the lie.

### Automatic Lying

Experts on lying debate about whether automatic lying, which sometimes has an additional effect that liars create false beliefs in other people, necessarily implies that automatic liars intend to deceive another person. These lies are expressed not with the means to create a false belief in another person but with the means to serve the self or to deceive as an end.

Taken together, lying often occurs intentionally: people generally engage in deliberate thought before they decide to lie and have reasons for lying. Lying, however, can also occur automatically. When the lie response is automatic, one can question to what extent people lie with a real intent to deceive others, as it might be an unforeseen byproduct of achieving their goal.

## Lying, Prevalence of

Prevalence refers to the extent or commonness with which something occurs in a population. In deception, the prevalence of lying is taken to mean the proportion of a population that engages in lying behaviors. Many scholars consider lying ubiquitous; that is, everybody lies. A related concept is the incidence of lying: incidence is the rate at which a behavior occurs in the population during a specific interval of time. Research in the United States suggests that people lie at the rate of one or two lies per day.

Estimates of prevalence and incidence depend on how broadly or narrowly the behavior is defined. When applied to all types of lies, prevalence and incidence are likely to be greater than when applied to more narrowly defined classes such as white lies, paltering, or exaggeration. The extent of lying also varies across subpopulations. Studies have shown that younger people lie more than older people, and men or women lie more than members of the other gender depending upon the circumstances. Within a population, low-incidence liars, including those who do not lie on a daily basis, may be classified as everyday liars, while those who lie on a daily basis and with great frequency are considered prolific liars.

Prevalence is an important aspect of scientific inquiry in many disciplines. Examining prevalence—and the related measures of event incidence, frequency of events, and intensity of events—is most common in epidemiology and provides a statistical basis for studying health risk factors and disease transmission. It is also used frequently in the examination of antisocial and socially undesirable behaviors such as alcohol and drug abuse, sexual deviance, prostitution, rape, and murder. In these areas entire publications, such as the *Journal of Substance Abuse*, are devoted to establishing the extent and nature of a phenomenon. Although lying and deception are societal norm violations and part of the class of behaviors considered to be socially undesirable, the presumption of ubiquitousness appears to have precluded much serious investigation into the extent to which people engage in lying or how the prevalence and incidence of lying may vary across subpopulations.

The antecedents of human deceptive behavior strongly support the view that lying is

ubiquitous. Charles Darwin noted that deception and the ability to detect deception are an important part of natural selection in the evolution of plants and animals. The traits of deception and the ability to perceive deception are adaptations of information processing skills that enhance the survival likelihood of an organism. At the cellular level, cancer cells mimic healthy cells in ways that allow them to be accepted by the host. Plants create camouflage in order to avoid being consumed, and most animals used a variety of deception strategies in order to evade predators, capture prey, mate successfully, and promote the well-being of the species.

Humans have inherited similar deception abilities as one component of their biological imperative and, with the acquisition of language, have refined deception and detection as social interaction and communication skills. Despite the moral and ethical concerns of philosophers such as Immanuel Kant, who declared all lying wrong, and Sissela Bok, who described lying as the essence of a dysfunctional society, nearly all humans utilize lies as a social lubricant to avoid conflict. For many people lies are also purposeful behaviors, used when it appears that telling the truth will not help them to achieve their goals.

### Studies of Prevalence and Incidence

Until recently, documenting the prevalence and incidence of lying has been quite limited. Biological antecedents and philosophical investigations of the morality of truth and lies have led deception scholars to the assumption of ubiquitousness. Individual life experiences have reinforced this belief. In the social sciences, a single study reported in 1996 by Bella DePaulo and her associates has served as the primary citation that lying is part of everyday life and that most people tell one to two lies per day. Two samples, a group of students and a group of nonstudent adults, kept diaries of their social interactions that included a record of the lies told. DePaulo reported that adult subjects recorded lying on average one time per day while college students recorded lying two times per day. Overall, 99 percent of the students and 91 percent of the adult subjects reported at least one lie during the week-long diary record-keeping; these results provide support for the assumption of ubiquitousness.

Beginning in 2010, large-scale studies of lying frequency were conducted in the United States, United Kingdom, and the Netherlands. This research has added empirical support to the idea that lying is widespread. In the United States, a cross-sectional survey of 1,000 adults found that on average people tell 1.65 lies per day, but only 40 percent reported lies in a given 24-hour period. The U.S. research also showed that in the course of a week more than 90 percent of the population tells at least one lie; study results confirmed that prevalence increases as the duration of the measurement interval increases.

In the United Kingdom (UK) study of nearly 3,000 adults, the average was calculated as 2.08 lies per day, with 76 percent reporting lying behavior on an average day. Within the UK, the only major geographic deviation was that of Northern Ireland, where subjects reported 3.50 lies per day and 84 percent reported lying on an average day. In the Netherlands, an experimental study involving 527 university students revealed an average of 2.04 lies per day, with 59 percent reporting lying behavior in a 24-hour period.

The elements of prevalence and incidence, as applied to lying behavior, are frequently confused. Average incidence reports of one to two lies per day suggest that every person tells one or two lies each day. This interpretation is reinforced by the assumption of ubiquitousness. Although researchers recognize that these estimates are derived from sampling data and accept that actual behavior may vary by individual, the common assumption has been that the estimates represent individual response that are normally distributed around the calculated means.

Data from the large-scale surveys and reanalysis of several smaller diary studies have revealed that the results do not have the normal bell-shaped curve distribution. Rather, data from all of the studies reporting incidences are positively skewed and asymptotic. When the number or percentage of subjects (Y-axis) is plotted over the number of lies told (X-axis) the shape of the distribution has a long tail that approaches zero only as the number of lies told grows large. The majority of subjects in these samples reported telling few or no lies per day, but a few subjects told more than the average number of lies. The larger the sample size, the more likely that at least a few of these

individuals will report telling substantially more lies than average.

### **Prolific Liars and Everyday Liars**

The few liars who tell lies with much greater frequency than the rest of the population have been referred to as prolific liars. These prolific liars are distinctly aggressive with their lying behaviors. In the study of U.S. adults, 5 percent of the subjects told more than 50 percent of all of the lies in a 24-hour period. Over time, most people will tell a few lies even if they do not lie every day. The everyday liars are more prevalent in the population but account for a much lower incidence of lying.

Statistical analysis of the distribution of lies suggests that prolific liars are a different subpopulation than everyday liars. When lying data for a specific population are examined, most of the subjects sampled report lying frequency in a narrow range from zero to a few lies. The data are Poisson-distributed; that is, the mean and variance are equal and the number reporting lying behavior drops off rapidly as the frequency of lies increases. Prolific liars are outliers of the Poisson distribution. Data for the prolific liars tends to be asymptotic and have been described with a power function. While the mean of the overall distribution provides a measure of average incidence, the break point between the Poisson and power functions serves as an indicator of the upper boundary for normal lying behavior.

Comparison of the large U.S. and UK studies suggest that in the United States up to two lies per day is considered normal and acceptable for everyday lying behavior. In the United Kingdom up to four lies per day is the normal and acceptable limit for everyday lies. When the frequency of lying exceeds these levels, the number of lies told is considered prolific and beyond the limit of normative behavior for the population being described.

Lying is prevalent. Though widely practiced it occurs with substantial variation of incidence across individuals. This holds several implications for research and for society as a whole. Because lying is nearly ubiquitous, some amount of lying is considered normal but only to the point that it does not exceed the standard for a population. Generally, the number of lies told on

a given day is likely to be a small proportion of the total communication in which people engage. This is both a positive and a negative. Limiting lying behavior reinforces societal norms, but it also means that most people use and expect truthfulness, making them more susceptible to being deceived by skillful liars.

For researchers, the presence of wide variations in individual differences, especially the differences between everyday and prolific liars, means that correlating the extent of lying with other characteristics is important. It also means that it is not sufficient to assume that lying is ubiquitous when studying individual behavior. For accuracy, deception research needs to control and account for individual differences in the production of lies.

## Lying as Ability or Skill

Although there is an extensive literature on the detection of lying, the literature on lying as an ability or skill is substantially smaller. The ability to lie skillfully for successful social interactions (the so-called white lies) as well as for interpersonal manipulation and personal gain would seem to be a valuable skill with an evolutionary history. Children begin to lie at an early age and become more skilled at lying as they mature. Adults tell lies to obtain employment and to impress potential sexual and romantic partners. Convincing lying seems to be a cognitively demanding task that requires inhibition, memory (to keep track of one's lies), attention, and the monitoring of one's own verbal and nonverbal behavior as well as the reaction of the listener.

### Development of Lying Ability

Children begin spontaneously telling lies very early, but the lies of 2-year-olds are remarkably unconvincing. Young children have difficulty maintaining lies and will often reveal information that clearly exposes the falsehood. As children get older, they become more skilled at keeping truth and lies straight and can produce answers to follow-up questions that are consistent with the original lie.

There is some evidence that, in regard to children's lying, practice helps. Children in harsh, punitive environments quickly learn to use lying as a means of avoiding punishment, so it is no surprise that they lie more frequently than other children; however, they also tell more sophisticated lies than their same-age peers, demonstrating greater ability to maintain their falsehoods in response to questioning.

*Young children have difficulty maintaining lies and will often reveal information that clearly exposes their falsehood. Children become more skilled at keeping truth and lies straight as they get older, producing answers to follow-up questions that are consistent with the original lie.*

In addition to practice, one reason that children get better at lying with age seems to be that the skills of inhibition, memory, and theory of mind (the awareness that others have intentions and desires that are different from one's own) improve with development. In general, lies can be broken into three components: primary (untrue statement), secondary (taking the other person's lack of knowledge into account), and tertiary (maintaining the lie with other statements). While inhibition is likely important for the primary aspect—the initial false statement and withholding of truth—theory of mind is important for the secondary aspect and working memory for the tertiary aspect. Given that most people are not particularly good at the detection of simple lies,

it may be that skills at the secondary and tertiary stages are most important to successful lying. If the deceiver cannot maintain the lie successfully and keep track of what the deceived person does and does not know, the falsehood is more likely to be detected.

Among older children and adolescents, these skills continue to be important. Older adolescents tend to be more effective at telling lies than younger adolescents, and adolescents rated as more socially competent tend to show greater lying skill than those rated as less socially competent. Cumulatively, this evidence suggests that lying, like other skills and abilities, improves with development and practice.

### **Cognitive and Neurological Correlates of Lying**

Executive functions (that is, the cognitive processes involved in planning, attention, working memory, and inhibition) are likely to be important in lying. Research has shown that the prefrontal cortex, which is associated with the executive functions, is activated when people lie. In general, telling lies seems to be more cognitively demanding than telling the truth. The lie-teller must formulate a lie, suppress the truth, monitor his or her own verbal and nonverbal behavior, and also monitor the other person's reactions to the lie. The important role of planning for successful lying can also be inferred from the fact that lying takes longer than truth-telling, and that hesitation or uncertainty can be a clue to deception. Those who are quick thinkers may, therefore, be superior liars as well.

Furthermore, when people tell lies in cognitively demanding situations (in research contexts, for example, people might be asked to tell their story in chronologically reverse order), they tend to contradict themselves more, use less detail, and tell less plausible stories than when they are able to devote greater cognitive resources toward lying. This finding suggests that having stronger executive functioning ability may counteract these potential "tells," allowing liars to maintain credibility even in stressful or otherwise cognitively demanding situations.

Recent neuroimaging studies have also implicated the amygdala, a limbic system structure known to be involved in emotional processing, as playing a role in deception. This makes sense,

given that control of emotion, planning, and memory are required in the successful telling of lies.

### **Verbal and Nonverbal Indicators of Lying**

It is often assumed that “twitchiness” and lack of eye contact is indicative of lying. However, research has identified a rather different pattern of behaviors associated with lying. For example, a recent meta-analysis on nonverbal indicators of lying found that blinking, eye contact, and postural shifts were unrelated to lying. Instead, lying was associated with reduced levels of hand movements, foot/leg movements, and nodding.

In terms of verbal behavior, research has indicated that lying is associated with changes in the pacing of speech (typically deceleration). Also, telling a lie generally takes longer than telling the truth. When lying, people tend to use a higher pitch of voice, take longer to respond, and make more grammatical errors and false starts in their stories.

Finally, the level of detail in a lie does not seem to be important to believability (assuming it is not inaccurate detail that alerts the other person to the deception). Planning, however, does seem to make a difference. When people are induced to lie without time to plan (that is, taken by surprise about the need to lie), they are less convincing regardless of the level of detail they include in the lie.

### **Individual Differences and Lying**

The tendency to be dishonest, which includes lying and other forms of interpersonal deception, can be seen as a relatively stable, trait-like characteristic. Both dishonesty in general, and the propensity to lie in particular, show evidence of substantial heritability that is in keeping with that of other personality traits.

Individuals with high levels of psychopathic traits (for example, interpersonal manipulation, callousness, lack of empathy, irresponsibility) believe themselves to be skillful liars. In a sample of corporate professionals, psychopathic traits were positively correlated with communication skills, as rated by colleagues. This finding suggests that chronically deceitful tendencies are not detected by coworkers or, if they are, these tendencies are not seen as indicative of poor communication. Also, in a study in which participants responded to emotionally evocative images with deceptive facial expressions, high levels of

interpersonal manipulation were related to less emotional “leakage” of genuine emotions, suggesting that manipulative traits might be related to success in some aspects of lying.

In keeping with this finding, individuals who are more manipulative tend to experience less guilt when lying, find lying easier, and feel more confident about their ability to deceive. Conversely, those who are anxious or self-conscious feel more guilt when lying, and find it more difficult to lie. Confidence and ease of lying appear to translate to skill, as people who are more expressive, extroverted, and have greater social control are better deceivers than those who are socially anxious. In fact, such expressive and socially skilled individuals seem to be more believable and better-liked whether they are telling the truth or lying, suggesting that possessing good social skills may facilitate believability in general.

People who lie frequently tend to believe their own lies to a greater extent than infrequent liars, which may enhance the skillfulness of these lies. When people believe their own lies, they reduce the cognitive load of the lie. They no longer need to monitor their own lies and monitor the reaction of the other person. Also, the guilt and anxiety associated with lying is diminished when the liar concurrently self-deceives, and the liar may be better able to avoid any telltale verbal or nonverbal cues associated with deception.

In one study, the ability to lie successfully was associated with the tendency to be able to successfully detect lies, leading the authors to propose the existence of an evolved general deception ability, rather than independent lying and lie-detection abilities. In this same study, there was no relationship between lying success and general intelligence. This finding warrants replication, as most specific cognitive abilities are intercorrelated and tap into a common factor of general intelligence. It would be of scientific interest to learn whether lying ability is or is not associated with either verbal ability or general cognitive ability.

### **Assessment of Lying Skill or Ability**

One possible explanation for the paucity of research on lying ability is the difficulty of assessing adults' lying. A typical research paradigm has participants video-recorded while telling both lies and truths, with others evaluating the truthfulness

of the statements. Quite often, these lies are of the “low stakes” variety and are lacking in ecological validity. Participants might be lying under instruction from the experimenter, thus greatly reducing the anxiety typically associated with social deception. Some paradigms involve a confederate asking the participant to lie, presumably inducing some guilt and anxiety in the participant who believes the experimenter is being deceived. Researchers studying children’s lying, on the other hand, often create situations in which children are motivated to lie to hide a transgression (for example, peeking at a toy after being instructed not to).

Another issue is having others rating the truthfulness of the stories. Research has shown that people are notoriously poor (often little better than chance) at detecting lies. Thus, some researchers have chosen to analyze more objective indicators of lying skill, such as the ability to retain a speech pattern that is consistent between lies and truths. Given the small effect sizes of verbal and nonverbal indicators of deception, this method would also seem to have drawbacks.

Some studies have incorporated self-report measures of lying ability. Although there appears to be some relationship between confidence in lying and success in lying, there is little reason to assume that self-report lying ability is a proxy for actual lying ability.

## Lying as Exercise of Power

Power is the ability to influence others and is based in structural, cultural, or societal sources of power, such as one’s class, sex, occupation, or position, or personal characteristics, such as charisma, social skills, poise, and dynamism. Leaders often possess these personal qualities as well as the structural sources of power, which gives them a great deal of influence over others. Leaders may use their power to deceive or may use deception as a tool in their persuasive repertoire more than those who lack the structural or personal sources of power. Research into deception and power has studied a variety of power relationships, including those in the workplace, educational settings, law enforcement, politics, and health care, among others.

Power should be differentiated from other related constructs such as dominance, leadership, authority, control, or influence. Generally, power is seen as the ability to exert influence on another person, but it is not always exercised in every situation. There are many different sources of power, including the legitimate status one has, the ability to reward or punish others, and the information or resources that one has access to. Powerful people do not always dominate others, because the situation or context determines what course of action is appropriate. In addition, having power in one context does not equate to power in all contexts because power is relationship and context dependent. Thus, when examining lying as an exercise of power, it must be examined with the context in mind in order to understand the motivations of deceivers and to understand what purpose their deception might serve.

Power is often associated with dominance and leadership, and some research suggests that deception is used differently by those on different rungs of the power ladder. Thus, powerful people may be more believable when they are lying not only because their status confers credibility but also because they look poised and confident when they are lying and have the social skills to weave deception and truth together. This combination of credibility and a skilled performance makes their deceptiveness very difficult to detect, especially when lies and truths are embedded together.

### High-Power Versus Low-Power Individuals

It may also be seen as more acceptable for high-power individuals to lie than low-power individuals because they may have access to information the low-power parties do not. For example, it might be seen as permissible for an employer to avoid telling his or her employees about an upcoming merger or even lie about knowledge of the merger because of the legal ramifications associated with the secrecy of the deal. It may also be seen as more acceptable for a doctor to mislead a patient about the certainty of smoking-related health effects than for a patient to lie to the doctor about how many cigarettes he or she smokes. Of course, different cultures have different interpretations of lie acceptability as well as different understandings of power, and so the cultural context should always be considered when discussing power and the social acceptance of deception.

Deception is often used as a bargaining tactic, and the power position of the parties may determine what strategies are used during negotiations. For example, because deception is often seen as unethical, it might be reserved as a tactic of last resort or may be seen as permissible only when the ends justify the means. Some research suggests that the power level of the negotiator influences the type of deception that is employed. Most people equate deception with falsification, or deliberately creating misleading statements, but other kinds of deceptions, such as vagueness, exaggerations, concealments, or omissions, are also available strategies. Omissions are deceptions in which certain facts are concealed and tend to be used less often by high-power individuals than low-power individuals. Powerful people are also more likely to question the lies of others, especially low-power individuals, because they do not face the same chilling effect or fear of repercussions as those in low-power positions face.

When deceiving, people have the choice whether to adopt a “fight” or “flight” approach. If deceivers choose to be aggressive or dominant, then they would likely try to convince others that they are being truthful. They would attempt to display certainty, confidence, and dominance and might use long narrative utterances that explain their position. In addition, if others display suspicion or disbelief, deceivers may become more

adamant and perhaps even combative in their reaction. This style would be interpreted as more powerful by observers because of its dominant style.

On the other hand, deceivers could choose a more passive approach. In this case, they might choose vagueness or concealment as the appropriate approach to avoid scrutiny and evade detection. This would appear to outsiders to be a more submissive communication style and thus, appear less powerful. Which style a communicator chooses will depend on his or her situational and relational goals. If their primary goal is to evade detection, they might choose a passive approach. If their primary goal is to persuade others of something that is untrue, they might choose a more aggressive and dominant approach.

In addition, the motivations behind deception are often different depending on the relative difference in power level of communicators. There are many reasons why someone would choose to lie rather than tell the truth, including preserving one's status, protecting the feelings of others, gaining financial or other tangible benefits, avoiding confrontation, or maintaining one's privacy. High-power individuals may be more likely to have motivations that protect their position and maintain their credibility, while low-power individuals may be more likely to have motivations that protect them from harm and/or equalize their power position if they find it to be unfair. For example, both teachers and students may lie to one another when they are late to class and both are trying to protect their credibility in front of the other. However, the teacher may be more concerned with preserving his or her image in front of the students, while the student may be more interested in avoiding punishment for tardiness.

### Deception as an Empowering Act

So, while it is likely that power makes deception more difficult to detect and more acceptable to perpetrate, it is possible that the link between power and deception also goes another way. Deception also confers power on the liar by the virtue that deception itself is an empowering act. Power comes from a variety of sources, but one source is having information that others are lacking. Investigations studying why patients lie to their physicians suggest that patients may

be trying to restore some of their lost power because of the invasions of privacy and the lower power level that are inherent for patients in the doctor-patient relationship. Keeping information from their doctors may give patients a sense of empowerment that they are lacking in the relationship. Recent investigations on the empowerment gained through deception suggest that the very act of deception, either because it is an act of defiance of social mores or because it simply means the deceiver knows something his or her partner does not, is in and of itself a source of power. Thus, deception may be both a source of power and evidence of underlying power structures within society simultaneously.

## Lying as Norm in Social Interactions

The acceptability of lying has been, and remains, an intensely debated philosophical and moral issue; however, there is nonetheless a growing body of research supporting the idea that lying is indeed a part of everyday life and social

interactions. Deception prevalence studies with college student and community member participants have reported that people lie about one to two times a day. Lying is like other communication behaviors in that it is often goal-oriented, and people lie in everyday life for many reasons and to achieve various goals. One prevalent reason lying is a norm in North American society is because politeness is generally an upheld value. Thus, people are even encouraged to lie in certain situations in order to protect others' feelings and to be polite. Although some may view any and all lies as immoral, others argue that telling only the truth, and nothing but the truth, can incur great harm to oneself and others.

One might ask, "Is deception really a norm in social interactions?" One way to answer this question is to determine how often people lie during social interactions in daily life. The most-cited deception prevalence study was conducted by Bella DePaulo and her colleagues and was first published in 1996. In this study, 77 college students and 70 people recruited from the community completed a diary entry every time they lied to another person. Overall, the study found that college students lied about twice a day, which was about once in every three social interactions. The community members lied about once a day, which was about once in every five social interactions.

Since this hallmark study, social scientific studies regarding the prevalence of deception in social life typically also ask participants to complete diary entries in a small book or electronic device every time they lie to another person. The participants are also usually asked to include details regarding the context of the lie, such as to whom the lie was told, the nature of the relationship, the topic of the lie, and/or their motive for telling the lie. Numerous other studies have addressed the prevalence of lying in social interaction and have generally found similar results. However, Kim B. Serota, Timothy R. Levine, and Franklin J. Boster's reanalysis of numerous deception studies found that on average, people tend to lie one to two times a day, but most people tell few or no lies a day and a few people tell more lies per day. Accordingly, while individual differences affect rates of lying per day, deception does appear to be a part of social interaction.

### **Motives for Lying**

While many value honesty as personal and relational attributes, people may nevertheless lie when they feel that lying will serve their goals better than honesty. Lying, like many communication behaviors, is often used to fulfill some type of goal. If one can achieve a certain goal through honesty, the person will more than likely be honest in that situation. Conversely, if a person believes that complete honesty will not achieve a goal, then he or she may lie in order to achieve that goal. As in many other "honest" social interactions, people may lie in order to make a good impression, regulate conversations, support others, or persuade.

There are many other reasons people lie, such as to entertain, protect their privacy, protect others' feelings, or excuse their own behavior. Accordingly, some scholars categorize lies by "high-stakes" lies versus "low-stakes" lies. High-stakes lies, such as perjury or fraud, have greater personal, social, and/or legal repercussions than low-stakes lies. Generally, white lies, or lies with low stakes, are more acceptable than high-stakes lies because the consequences of the lie or of the truth being revealed are not as severe.

In addition, scholars further categorize lies based on motives—whether the lie was told to serve the liar's interest or to serve the interest of the person who was told the lie. Generally, altruistic lies, or lies that benefit another, are more acceptable than self-serving lies because the goal of the liar is to somehow benefit the other person. However, identifying motives for one's behavior can be difficult; even if a liar believes the lie was meant to benefit another, the person who was lied to may not agree.

### **Lying as a Social Lubricant**

Regardless, some white lies may be considered permissible in North American society, and white lies are even encouraged in some situations. The value of politeness plays a large role in the acceptability of white lies. For example, many parents teach their children that lying is even the right thing to do in some circumstances. Before birthdays or holiday events, parents may tell their children that they should thank someone for a gift and tell the giver they like the gift even if they do not because it is the polite thing

to do. Children are also socialized to censor their opinions because true statements could cause awkward situations or hurt a person's feelings. In other words, children are taught that telling the truth can be rude or hurtful and should be avoided in some situations; thus, lying is sometimes the right thing to do in order to protect others' feelings.

As adults, people also frequently use deception in order to be polite to others. If a close friend is seeking comfort after an unfortunate haircut, a person may lie to the friend in order to give them reassurance and support. To complicate the issue, the friend may not even want to hear the truth: "Yes, that haircut looks horrible, but there is nothing you can do about it now except let it grow back." In these cases, is it a societal norm to even expect to be lied to in some circumstances? For some, a lie may be far more comforting than the truth. Truth can sometimes be a bitter pill to swallow so, as a society, people are socialized to lie in some cases because it may be considered the right thing to do.

These types of lies act as a type of social lubricant because lying helps one avoid awkward situations, hurt feelings, insult, or conflict. Lies may even protect a person's need for privacy in some matters. For example, if a person hears terrible news from a family member on the phone and then immediately crosses paths with a coworker who asks, "Are you okay?" an expected response may be to lie in order to maintain a sense of privacy. An acquaintance who asks, "How are you?" might even find a truthful response of "Awful" to be inappropriate and unwarranted. Again, although honesty is generally an upheld value, lying can function as an expected and acceptable part of everyday interactions, even if the truth of this statement is unsettling. People may not want to view themselves as liars, but complete and incessant honesty could lead to various negative personal, relational, and social consequences.

For example, A. J. Jacobs, an editor at *Esquire* magazine and author of three *New York Times* bestsellers, decided to try living a life of "radical honesty" as part of a book project that placed him in various life "experiments." Jacobs tried to be completely honest for a one-month period. He did not succeed at being completely honest and

even wrote in his book, *The Guinea Pig Diaries*, that the experiment to practice radical honesty was "probably the worst month of my life." He wrote that his experience was fraught with the ups and downs of complete honesty—from the exhilaration of authenticity and having others reciprocate to the embarrassment, conflict, and even borderline sexual harassment that ensued from telling the whole truth. Jacobs wrote that if he had indeed been brutally honest about what he was thinking and feeling all the time, he would probably have "gotten beaten up, fired, and divorced."

### Lying for Protection

Another reason lying could be considered a norm in society is that sometimes the information covered by the lie may be more damaging than the lie itself. If an employee is late to work because she overslept, she might tell her boss she was stuck in traffic. If a friend asks another friend out for dinner but he would rather not go because he finds the friend to be boring, he might say he has another engagement. If a sibling asks her brother if he likes her new painting, he may say he does even if he does not. In these cases, one might argue that the truth may be more damaging to the relationships than lying would be. The employee is excused from being late while the friend and sibling are saved from having their feelings hurt. Conversely, others might argue that people should take responsibility for their actions, be honest about their feelings, or that it might even be compassionate to give honest, yet potentially hurtful feedback to others in order to better help them. Regardless, these types of lies are common in society because sometimes it is simply easier to lie than to face the repercussions of the truth.

Some philosophers and writers, such as Sissela Bok, Jean-Paul Sartre, and Immanuel Kant, believe that lying is immoral and has devastating consequences for the liar, the ones being lied to, and perhaps even society. Conversely, others might argue that lying is only immoral when it causes more harm than good. Others, such as DePaulo, argue that telling the complete truth all the time may not even be possible, and if it were, it may not be the desirable choice for those involved. Others argue that lying is a necessary

part of life or even the moral thing to do in some circumstances. Regardless of one's attitudes about lying, it is indeed a norm in everyday interactions.

## Machiavelli, Niccolò

Niccolò Machiavelli (1469–1527) was an Italian political theorist, philosopher, and diplomat, whose life and works have acquired for him a reputation as a master in the dark arts of deceit and manipulation. His writings were wide-ranging, addressing many of the concerns of the Renaissance, and encompassed history, poetry, and drama. But it is as a foundational writer in modern political science that he is most renowned. The best-known and most influential of his works is a treatise titled *The Prince* (published posthumously in 1532, although notorious in manuscript form for 20 years before then). Largely as a result of this book, commentators and critics began to adopt the adjective *Machiavellian*, which has become a byword for the description of plotting, scheming, double-dealing, and subterfuge—usually in a political context. Whether this reputation is fair, however, given the subtlety of Machiavelli’s numerous works and their wide-ranging content, has been the subject of much revisionist speculation, particularly in the 20th and 21st centuries.

Machiavelli believed that—if possible—citizens should have a role in deciding their own form of government, and his writings taken as a whole suggest various modes of governance as appropriate to differing political climates. He took his own civic and official responsibilities seriously,

and served the Florentine Republic for 14 years in a number of roles, including chief of the Florentine militia and superintendent of its defence forces.

Throughout this period he was a supporter of the Borgias, a powerful dynastic clan, and historic enemies of the Medici, celebrated Renaissance patrons of art. In 1512 the Medici family returned to power in Florence and Venice and undertook a program of revenge against their foes, the Borgias among them. Machiavelli, suspected of plotting against the Medici, was imprisoned and subjected to torture. Following his release, he was excluded from public life and retired to his farm outside Florence, where he wrote his most influential works, *The Prince* and *The Discourses on Livy*. Machiavelli’s exclusion from the exhilarating turbulence of political life led to loneliness and dejection, although he was able thereby to gain the perspective on concepts of authority and power that informed his writings with the enduring relevance they retain today.

Much of Machiavelli’s reputation (if not notoriety) rests on the statements about power that he makes in *The Prince*. His preoccupation is with how to achieve and then maintain authority, considered a good end in itself, and his ideas are couched in the form of advice to a hypothetical “new prince”; that is, one who is striving for authority through political planning rather than

inheritance or entitlement. In this context he became famous for promoting the concept that “the ends justify the means.” The suggestion is that a leader can and must do whatever is necessary, by any means possible, in order to lead. This has consequences that caused outrage during Machiavelli’s lifetime and which have continued to be problematic ever since.

For example, many of the decisions a prince would have to make, following Machiavelli’s recommendations, are in contradiction to received standards of ethics and morality: indeed, in certain situations a prince would be obligated to act immorally. Machiavelli sanctions this behavior so long as stability and order are upheld. The ideal leader, for him, must construct an identity, or persona, guaranteed to command respect. According to *The Prince*, there will be cases in which a leader should strive to be feared, and this may

entail tyrannous or cruel behavior. In other cases, however, it may better suit a leader to show mercy and compassion.

What is uppermost is the need for a prince to retain popular respect, so that he can govern unimpeded. If this requires lying and deception, then so be it. Machiavelli does not, in other words, seem to adhere to the standards of absolute morality—unmoving principles of right and wrong—which are generally referenced in treatises of this kind. Instead, his advice is to act according to the changing circumstances of fortune or fate: when those circumstances alter, so must the action taken by a leader. This constituted a blatant challenge to the doctrines of the church, in which ethical principles were held to be absolute, but Machiavelli’s answer would always be that he is merely showing human beings as they really are, rather than as they think they are.

Stefano Ussi’s *Niccolò Machiavelli in His Study* (1894). Machiavelli, an Italian political theorist, philosopher, and diplomat, is most known for his foundational writings in modern political science. His best-known and most influential work is *The Prince*, widely circulated in the early 16th century and published posthumously in 1532, in which he focuses on the means to achieve and maintain authority. In this context, he became famous for promoting the concept that “the ends justify the means,” which includes deception.

His appeal is to honesty about the human condition, rather than transcendent or supernatural standards of ethics. To some, this fluid code of conduct has appeared to advocate totalitarianism and autocracy, seeming not only undemocratic but also antidemocratic, with Machiavelli as a slippery “operator” who is impossible to pin down. Machiavelli himself, near the end of his life, was quoted as writing, “I have never said what I believe or believed what I said,” and that “if indeed I do sometimes tell the truth, I hide it behind so many lies that it is hard to find.”

This view, however, does not paint a complete portrait. Other readers of Machiavelli have been positively influenced by his assumption that morality—especially in the political arena—is a human, not a divine, construction, and must therefore take account of the real motivations of humans, which are often murky or ambiguous and always prone to error. They claim that his focus on deception is concerned not merely with the desire to deceive but also with the necessity of recognizing that one may become the victim of deception oneself. In this sense, Machiavelli is an advocate of what much later came to be known as *realpolitik*—the politics of brinkmanship, power, and pragmatics, rather than fixed ideology.

Defenders of Machiavelli also point out that his worldview must not be identified solely with *The Prince*. In his longer work, *The Discourses on Livy* (posthumously published in 1531), Machiavelli selects examples from the history of ancient Rome to argue the case for republican, rather than princely, leadership, proposing that a well-regulated republic may in some situations actually offer a safer and more just form of governance than the principdom advocated in *The Prince*. Both these works suppose that models of government drawn from historical or contemporary political circumstances are more likely to succeed than models generated by idealism or unrealistic expectations, and that requiring politicians and populations alike to confront realities, rather than insecure ideals, will secure human dignity and help dispel illusion and false hope.

## Machiavellianism

Niccolò Machiavelli was an Italian philosopher, statesman, and political theorist. He is well known for his treatise *The Prince* (published in 1532, although known in its manuscript form for 20 years before that), in which he advocated that a ruler be exploitive, manipulative, and deceitful in order to gain success in a socially competitive and status-oriented society. The main intent of *The Prince* was an evaluation of traditional moral norms regarding power, with Machiavelli maintaining that a ruler should disregard moral norms and only be concerned with gaining power and authority.

Machiavellianism, as addressed here, is a term used in the social behavioral sciences to describe an individual's tendency to be emotionally cool and detached, which enables an individual to disengage from morality, making it easier to deceive and manipulate others. Essentially, Machiavellianism is synonymous with deceit and lying.

Machiavelli believed it was necessary to deceive in an imperfect world in order to rise to the top. When a truth is unlikely to serve one's purpose, a lie is used instead.

### Personality Traits of Machiavellianism

The concept of Machiavellianism in the social behavioral sciences comes from R. Christie and R. L. Geis's seminal work from 1970. Using the philosophy and forms of manipulation described in *The Prince* and also in Machiavelli's *The Discourses on Livy* (1531), they created a 20-item personality measure called the MACH-IV test (there is also a MACH-V measure, which is a forced choice version of the MACH-IV). People scoring high on the scale (high Machs) would be likely to agree with the item, "Never tell anyone the real reason you did something unless it is useful to do so." An individual scoring low on the scale (low Machs) would be likely to agree with the item, "There is no excuse for lying to someone else."

Individuals high in Machiavellianism tend to manipulate more, win more, and persuade others better through deception. In addition, those high in Machiavellianism tend to be better liars and feel less anxiety when lying. Interestingly, there is no association between the liars' disposition and intellectual ability. Machiavellianism also has been found to be linked to specific Big Five personality traits, for example, being negatively correlated with agreeableness and conscientiousness, and positively correlated with neuroticism.

### Dark Triad of Traits

Research on Machiavellianism was fruitful from the 1970s through the 1990s. However, in the 21st century there has been a growing application of Machiavellianism as part of the Dark Triad of traits, which includes three socially undesirable dispositions: narcissism, psychopathy, and Machiavellianism. Narcissism is seen as a subclinical or "normal" construct, which includes characteristics of grandiosity, entitlement, dominance, and superiority. "Normal" or subclinical psychopathy includes elements of high impulsivity, thrill-seeking, low empathy, and anxiety. Together, these three traits can be seen as a short-term exploitive social strategy that has evolved to be advantageous in social situations.

The elements of the Dark Triad share a number of features. The three dispositions are seen as socially negative with tendencies toward aggressiveness, emotional detachment, and self-promotion. In general, individuals with these traits are more self-serving and less involved emotionally and empathetically toward others, which facilitates the manipulation of others for their own gain with minimal remorse.

Research on the Dark Triad has found that those high in Machiavellianism are associated with an open, promiscuous, and hostile set of sexual attitudes. They were also associated with self-serving and deceptive sexual tactics, such as cheating, divulging sexual secrets, and faking love to secure sex. Narcissists and psychopaths have also been found to be noncommittal and prefer short-term mating strategies. Those higher in these dispositions were also found to have more sex partners, an unrestricted sociosexuality, and a greater preference for short-term partners using exploitive and deceptive tactics.

The Dark Triad of traits and Machiavellianism have also been investigated in the workplace setting, with individuals high in Machiavellianism more likely to use charm and manipulative behaviors in the workplace. In addition, individuals high overall in the Dark Triad of traits use forceful, aggressive, and other hard tactics of social influence in the workplace in order to gain success.

A standardized measure was developed by P. K. Jonason and G. D. Webster to assess the Dark Triad (called the Dirty Dozen) consisting of 12 items, four for each trait. A Machiavellianism item asks individuals to indicate how much they agree with the following statement: "I tend to exploit others towards my own end." Machiavellianism can be seen as a socially undesirable personality trait or disposition, with deceit and manipulation at its core. Researchers have done extensive studies on how this trait can be adaptive in both the workplace and in relationships. Not only do individuals with this trait tend to lie and deceive more, they lack the empathetic and remorseful response that an individual would normally feel, making it easier to manipulate and lie.

## Madoff, Bernard

Bernard Madoff, founder and former chairperson of Bernard L. Madoff Investment Securities LLC, ran a Ponzi scheme that caused its investors to lose an estimated \$17 billion to \$20 billion. Journalists, pundits, and finance experts have called the Madoff case one of the most extensive financial frauds in the history of the United States. After pleading guilty to 11 felonies, including securities fraud and money laundering, Madoff was sentenced to 150 years in prison.

A New York native, Madoff started Bernard L. Madoff Investment Securities in 1960. The firm was not a member of the New York Stock Exchange, instead functioning as a third-market provider and investment advisor. (A third-market provider allows individual investors or institutions to trade securities over the counter, rather than within a traditional stock exchange. For example, online trading is a third-market

transaction.) Madoff's firm grew in prestige when it contributed to developing technology allowing investors to buy and sell stocks electronically. This new technology later became the world's first electronic stock market, NASDAQ, which went live in 1971. Over time, Bernard L. Madoff Investment Securities became increasingly influential in the Wall Street world. Madoff himself was praised for his innovation and consistent success. Many members of his family joined the firm, including his sons, Mark and Andrew, and his younger brother, Peter.

In a Ponzi scheme like the one operated by Madoff, funds contributed by new investors are used to pay returns to previous investors, thereby making the investments appear to be profitable. As long as the operator is able to find participants, the scheme—which earns little or no money without new investors—can stay afloat. Madoff focused on attracting wealthy clientele, particularly among the upper-class, Jewish individuals and groups he encountered at New York country clubs and philanthropic events. He found many charitable organizations willing to invest—and these were attractive targets because they were unlikely to withdraw funds. Some of the charities eventually had to close when Madoff was arrested and the scheme collapsed.

While many Ponzi scheme operators win new investors by touting low-risk, high-return investment opportunities, Madoff eschewed such extremes, instead creating fake account statements showing consistent and good, rather than excellent, returns. In this way, he was able to avoid suspicion for a longer time than he might otherwise have done. When investors wanted to withdraw funds during the 2008 market downturn, they discovered Madoff's fraud. In December 2008, Madoff confessed to the scheme when he realized that he could not return a requested \$7 billion in redemptions. He was arrested shortly thereafter. His clients, victims of the fraud, included individual investors, hedge funds, public pensions, universities, banks, and charities. Madoff's 162-page clientele list also featured several well-known names, such as Nobel Laureate Elie Wiesel, film director Steven Spielberg, and Hall of Fame baseball pitcher Sandy Koufax.

Some financial analysts and business journalists suspected Madoff's wrongdoing long before his

eventual downfall, leaving many to wonder if the increasingly abstract and complex culture of Wall Street enables such frauds, and if the U.S. Securities and Exchange Commission (SEC) was too lax in enforcing existing regulations. Fraud investigator Harry Markopolos amassed nearly a decade's worth of evidence against Madoff, but his early warnings were not heeded by the SEC. Madoff's firm was investigated by regulators several times, but their findings were minor and never resulted in significant changes to the firm's business practices. Madoff's well-known secrecy—he even told investors that he would not answer questions because his methods were beyond their comprehension—may have helped him to avoid earlier exposure.

In 2013, Madoff was incarcerated at the Federal Correctional Institution Butner Medium in North Carolina. His combined assets (approximately \$826 million) were frozen. In 2009, the SEC banned him from ever working in the securities industry again; that same year, the SEC conducted an internal investigation of its conduct in an effort to discover why the agency failed to stop Madoff earlier. (Eight SEC workers were disciplined and none was fired.) The Madoff Family Foundation, a philanthropic institution he co-managed with his wife, Ruth Madoff, had its assets frozen. Mark Madoff committed suicide in 2010.

As of September 2012, about \$3.625 billion was returned to victims of the fraud—slightly more than half the amount Madoff stole from them.

## Magic Tricks

There are few forms of lying and deception as harmless and entertaining as magic tricks. From Dedi's animal "resurrections" in Egypt in 2600 B.C.E. to Harry Houdini's escapology and David Copperfield's illusions, magicians have been astonishing audiences for centuries, in a bidirectional relationship of performance and appreciation, entertainment and escapism, in exchange for willing credulity. What differentiates magic tricks from many forms of lying and deception is that deceit is not hidden. It is not malicious and typically not unethical. It is an agreement, part of a game accepted as a given for the sake of innocuous diversion.

### Magic Performance as a Form of Social Interaction

A magic performance can be considered a special case of social interaction in which performers and audiences implicitly and willingly agree to be the deceivers and the deceived, respectively. This social agreement defines the difference between what might be considered magic versus a scam or crime. Many illusions, for example, deceive the audience as to the location of an object, such as a coin, or even the magician himself. Such location illusions are likely to be labeled as "magic" when occurring at a Las Vegas showroom but as a "scam" when part of a street game of three-card monte designed to separate an unwitting victim from his money. Similarly, an audience may howl with glee when a stage magician strips a willing volunteer of his money, watch, and other detachables; whereas if a street thief uses exactly the same techniques for the same purpose, it is no longer magic or funny, but rather a crime.

Once the context has been established as a magic performance, the magician must enact his role as master of the seemingly impossible, confronting the audience with unexpected and incomprehensible actions and outcomes to evoke surprise and wonder. Though expecting (and even wanting) to be misled and tricked, audiences nevertheless attempt to unmask the mysteries and uncover the magician's secrets. How, then, have magicians so effectively deceived and entertained (even one another) for hundreds of years?

### **Magic as a Cognitive Process**

Master magicians have, for centuries, intuitively grasped at least six fundamental principles of perception and cognition that modern neuroscience has only belatedly come to understand. First, some things, though directly in a person's line of sight, are not perceptible at all. Second, people do not consciously perceive everything that can be perceived. Third, what is consciously perceived depends upon attention. Individuals will fail to see even what is in their direct line of sight or fail to feel an easily perceptible touch if their attention is elsewhere. Fourth, people sometimes misinterpret what they perceive. Fifth, individuals' memories fail in ways that permit changes to occur before their eyes that they do not consciously perceive. Sixth, these failures can be regularly and lawfully produced by specific manipulations of individuals' perceptual and sensory systems. Magicians use these basic principles of perception and cognition to determine what the audience does and (does not) perceive and how this perception is interpreted, employing manipulations of mind and objects to blur and misrepresent reality with literal and figurative "smoke and mirrors."

As science fiction writer Arthur C. Clarke famously noted, "Any sufficiently advanced technology is indistinguishable from magic." Magic only seems like magic when people don't understand the mechanism. This is true for every trick from the famous cups and balls demonstration to the night David Copperfield made the Statue of Liberty disappear. The greater the apparent violation of laws of physics and causality, and the less understandable the mechanism of the trick, the bigger the magic. The goal of the magician, then, is to perform the seemingly impossible while completely obscuring the mechanism by which it is accomplished.

### **Using the Imperceptible**

The simplest level at which the mechanism of a trick may be obscured is to cause it to be imperceptible. This occurs, for example, when the magician may pass his cape over the mechanism of action, cut a body in half that appears to be mostly inside a box, place the box over a hidden passageway, or use smoke and mirrors to obscure or deflect the line of sight.

Even if the line of sight is not blocked, the mechanism of action may nevertheless be imperceptible when the magician makes use of principles of perception to render part of the visual field invisible. A rather stunning class of illusions known as Black Art uses the principle of "perceptual contrast" to obscure the bodies and actions of the performers. Such illusions make use of a black stage with black backing, against which black objects (including persons dressed in black and in blackface) will be imperceptible, and light-colored objects will stand out. The performers dressed in black can create illusions by carrying out a number of actions invisible to the audience, but performed in front of their eyes. Objects may be carried across the stage even as they appear to float unaided; or may suddenly appear when black covers are removed by the invisible black agents. Though Black Art has been used for over 100 years, modern Black Arts magicians have added the use of black light to enhance their illusions. The magician may appear to paint an object into existence when he is actually painting an existing black object with a substance rendering it colorful under black light.

The magician's actions can also be obscured when an audience is made momentarily blind by sudden changes in lighting. For a few moments after such changes, the audience cannot see until "light adaptation" or "dark adaptation" allows their eyes to adjust. During those moments the magician can execute the mechanism of a trick directly in the line of sight of the audience without it being seen.

### **Attention and Misdirection**

Magic is perhaps even more impressive when the mechanism of action is not blocked from perception and instead is performed in a manner that could be perceived, if only the person were to attend to the right place at the right time. Nothing blocks the perceptions, but the magician successfully prevents the audience from perceiving. This is perhaps the most pervasive mechanism of magic: "misdirection," defined as any act or stimulus that will take the audience's attention away from the means of the trick. Misdirection relies on natural instincts to look where the eyes are directed (either by auditory or visual prompts); to orient to the onset of new stimuli (such as a flash

of light, the entry of a new person, or a touch); to respond, often subconsciously, to emotional stimuli; to attribute viable meaning to the movements of others; or to give way to carefully placed suggestion.

A successful magic trick will divert the audience's attention at just the right moment from the critical maneuver to an unrelated or confounding event. The magician may supplement distractions at the moment of the trick with subtle suggestions leading the audience to expect a different mechanism of the trick and thereby to attend to actions related to the incorrect mechanism. The magician may even go so far as to divert attention to the wrong trick. Master pickpocket Apollo Robbins was asked for a demonstration of his pickpocketing skills by master magician Penn Jillette. Robbins refused but offered to perform a different trick instead: instructing Jillette to first place his ring on the table and trace its outline with his pen. Jillette began to comply, only to discover that Robbins had pilfered the cartridge of his pen while his attention was diverted to the new trick.

Unlike most magicians, Robbins has widely discussed the mechanisms of his tricks, noting that he must be both master reader and master manipulator of the target's attention. He may first draw attention to an object such as a map or coin so that he can slip without resistance into the target's personal zone, where he now has access to the target's body, pockets, or purse. He then makes use of an arsenal of common tools of misdirection while he steals everything detachable without detection. These tools include distracting patter, eye contact, directing his own gaze away from the thefts (drawing the target's in the process), diverting gestures or touches, or asking questions that direct attention to certain actions or areas of the body. He may place his arm somewhere for one apparent purpose, when he is really blocking the target's view of a theft, restricting the target's movement, or temporarily stashing a stolen object before secreting it in his own pocket.

As he works, Robbins continually reads where the target's attention is directed, whether it needs redirection, and whether he can yet perform the theft. As Robbins explains, "It's all about the choreography of people's attention. Attention is like

water. It flows. It's liquid. You create channels to divert it, and you hope that it flows the right way."

### **Managed Misinterpretation**

Crucial to the magician's art is the ability to control audiences' interpretations of what they perceive. This ability is crucial, for example, to successful pickpocketing. Robbins explains that to prevent the target from recognizing that the magician's hand is in his pocket, the magician may give the target another apparent explanation for what he feels by brushing his own leg against the area of the target's pant pocket.

Much of the magician's managed misinterpretation relies on the power of expectations to shape perceptions. Even as the eyes physically see what has actually occurred, the brain can be led to "see" something entirely different. In the disappearing ball illusion, for example, the magician tosses a ball into the air and catches it several times before the final toss, when the ball appears to disappear into the air. The magician creates the expectation that the ball is tossed through his arm movement and by following the (presumably) rising ball with his head and eyes as he has on the other tosses. But through the use of eye-tracking technology, neuroscientists' scientific studies of this trick have shown that even though the audience members report having "seen" the ball tossed up, they actually do look at, and technically see, the magician transfer the ball to his other hand before the apparent toss. The strong expectations generated by the magician's actions appear to override the audience's physical perceptions.

### **Change Blindness**

Recall that a fifth mechanism of magic relies on fallacies of memory. Two are particularly important. First, people often do not encode sufficient detail into memory to allow them to reliably discriminate between similar people and objects. Second, individuals often fail to remember the detail they do encode long enough to compare it to things they see (even seconds) later. These two failures underlie a phenomenon cognitive scientists refer to as "change blindness," which is the failure to notice large changes that occur within one's visual field.

Change blindness underlies the success of a computerized "mind-reading" illusion by Clifford

*An illusionist demonstrates a card trick at the media preview of "Magic, the Science of Wonder" at the Houston Museum of Natural Science, February 27, 2010. Much of a magician's managed misinterpretation relies on the power of expectations to shape perceptions. Even as the eyes are viewing what is actually occurring, the brain can be led to "see" something entirely different.*

Pickover, which appears on his Web site, Pickover.com. Visitors to the Web site are asked to pick a card from an array of six face cards, stare at the card, and commit it well to memory. They are told the computer will be able to determine (psychically of course) which card visitors have picked, even though they have not clicked on it or otherwise indicated which one. When ready, visitors will click on a symbol, whereupon they see a five-card array from which they are told their card has been removed. The card for every visitor is no longer present, giving the illusion that somehow the computer knew which card the visitor had picked.

But the illusion relies on change blindness aided by expectation and misdirection. In fact, all cards from the original array were removed and different face cards were substituted. But the changes in other cards are not noticed. The visitors expected that their card would be removed, not that all of the cards would be removed, and when viewing the original array they were directed to stare at their own card, not the others, thereby enhancing their natural tendencies not to notice the change of all cards.

## Conclusion

The magic tricks described here are only a few of the countless mechanisms of perception and cognition used by master magicians. In many ways, these magicians have put cognitive scientists to shame—discovering, mastering, and using a great wealth of knowledge of the workings of the human mind centuries before scientists dreamed of investigating it.

## Malingering

Malingering is the falsification or exaggeration of physiological and/or psychological illness symptoms with the intention of receiving some sort of compensation or reward. Malingering is classified in two degrees: partial malingering, which is the extreme exaggeration of present symptoms, and full malingering, which is the complete fabrication of symptoms. As of 2002, approximately 29 percent of personal injury claims, 30 percent of disability claims, as well as 31 percent of cases regarding chronic pain and 8 percent of clinical disorder cases involved partial or full malingering.

Malingering has also been observed throughout history. The Greek physician Galen, who lived in the 2nd century C.E., noted patients feigning symptoms to avoid engaging in an unwanted activity. For instance, one slave faked a knee injury in order to avoid having to take a long trip with his master. Malingering was also very common in the Soviet Union. In fact, so many people

malingered as a means of escaping political and physical coercion that the government limited the number of allotted medical excuses that physicians could give to patients.

### Motivations for Malingering

It is important to emphasize that a malingerer is intentionally attempting to deceive others and is motivated by external gain, so as not to confuse malingering with other disorders involving deceptive presentation of illness symptoms. Malingering can be easily confused with Factitious Disorder, which is the intentional feigning of a disorder or illness with the intent of receiving medical treatment. Malingerers intentionally feign an illness or a disorder, but they do not do it to receive medical treatment. They do it as a means of gaining some benefit or reward, such as insurance money, or to appear unable to work or incapable of fulfilling other obligations. For example, there have been many accounts of people malingering post-traumatic stress disorder (PTSD). U.S. veterans with PTSD are able to receive many financial benefits (for example, Social Security disability benefits and financial compensation from the Department of Veterans' Affairs) to aid them in their coping process. Thus, many people who do not have PTSD have attempted malingering of the symptoms as a means of receiving this monetary compensation.

Malingering is considered an offense in the U.S. military, punishable by dishonorable discharge and incarceration of up to 10 years. Malingering is also considered illegal when it is done in order to fraudulently gain compensation. For instance, in January 2012, a woman from Virginia was charged with medical fraud after she claimed to have cancer in order to raise money from sympathetic supporters. There have been many other cases in which people have feigned having cancer or some other terminal disorder for personal gain, such as getting extra sick days from work, gaining money from charities, getting a free trip to Disney World, and getting one's lavish dream wedding for free (by having it paid for by sympathetic friends and family members).

Malingerers have also been known to go beyond simply feigning symptoms. For instance, malingerers who are seeking to increase their temperatures to exaggerate their symptoms (that is,

fever) may go so far as to heat their thermometer by using a lamp. Some may even alter their urine sample by adding sand to it, which increases the difficulty of gaining an accurate diagnosis.

### Models of Malingering

To date, there are three explanatory models regarding why people choose to malingering: pathogenic, criminological, and adaptational. The pathogenic model refers to people who already have an underlying abnormal psychological condition that causes them to malingering. This does not mean the patient is malingering symptoms of his or her underlying disorder; he or she is malingering symptoms of an illness or disorder as a means of gaining some personal benefit, such as money or sympathy. In other words, these patients may be unable to control their malingering in a way that is similar to how kleptomania patients cannot control their thievery.

The criminological model states that some people may malingering simply because they do not care about the legal or social ramifications of their actions and thus malingering as a means of gaining an undeserved reward or benefit. The adaptational model suggests that some people may malingering as a means of getting ahead in a highly competitive environment. In these cases, one may malingering in order to gain special treatment from his or her boss (for example, sympathy in the form of extended deadlines and/or not being fired for insubordination). Empirical support has been found for all three of these models.

The Minnesota Multiphasic Personality Inventory (MMPI-2) has been revised to include malingering subscales in order to detect malingering of psychological disorders. Specifically, the Infrequency-Post-Traumatic Stress Disorder Scale was developed with PTSD patients who had been exposed to military combat. It has helped detect the malingering of PTSD symptoms in civilian and military patients. Another subscale, known as the Malingered Mood Disorder Scale, was created and tested in 2008. It is successful at detecting malingering in personal injury and disability claims.

### Guidelines for Detecting Malingerers

Malingering can cause abuse within the medical system because these patients receive many unnecessary tests, and they waste the physician's

time when it could be used for patients who are legitimately ill. In order to help detect and reduce malingering, *The Diagnostic and Statistical Manual of Mental Disorders* (DSM-IV) provides four guidelines to determine when to suspect malingering of mental disorders. Suspicion should occur when (1) the diagnostic evaluation occurs in some legal context, (2) there is a discrepancy between the patient's claim and the scientific/objective findings, (3) the patient is uncooperative during the evaluation and refuses to comply with the prescribed treatment, and (4) the patient has antisocial personality disorder.

If a patient satisfies these criteria, he or she may be malingering. However, many critics have argued that these criteria are overly broad and may lead to the overdiagnosis of malingering. Although using these criteria leads to detecting approximately two-thirds of malingerers, it is estimated that about 80 percent of people with a true mental disorder will meet at least two of the four criteria.

Because malingering is not a disorder, there is no treatment for it. However, malingerers tend to stop malingering when they get their desired reward, or when they realize that malingering will not get them what they want.

## Manipulation

Manipulation typically involves deception to obtain a planned goal with lack of regard for another’s interests. A plethora of concepts are discussed in relation to manipulation: threat, constraining options, seduction, bullying, bribery, conditioning another, conning another, and conquering and dividing a group of individuals, to name a few. While manipulation may occur unintentionally, intentional manipulation, with all its moral overtones, is of the most interest to researchers simply because manipulation violates the trust between individuals and impinges on an individual’s free will; that is, individuals have goals and the manipulator’s deceptive practices limit or redirect the choices of the individual. The fact that there are no contextual or situational limits (that is, boundaries) for when a person can be manipulated explains the ubiquitous nature of manipulation and why almost everyone has a story to tell when asked if they have ever been manipulated.

A key issue involved in manipulation is ambiguity, in a variety of forms. This includes ambiguity as to whether the perceived manipulator is truly uninterested in the individual’s goals and desires, or merely misunderstanding and therefore pushing their own goals and desires. There is also ambiguity as to the perceived rationale for the manipulation: Is the supervisor merely managing for the good of the company, or is the teacher motivating the students to learn? There can also

be ambiguity as to whether another is actually manipulating an individual; because deception is involved in most instances of ambiguity, a manipulator does not typically admit to their manipulation and may deny it if confronted.

In each of these types of ambiguity, and in other forms not mentioned, doubt is introduced to the individual’s understanding of the situation, which can influence the individual in a variety of ways, such as causing the individual to withdraw from the interaction to the extent possible; to probe the situation searching for signals as to the legitimacy of any claims made by the potential manipulator; to remain tentative and refuse to challenge the possible manipulation, because there is no surety that manipulation is occurring; or to assume the other’s motives are acceptable and allow the manipulation to occur. These possibilities and more exist because of the doubt introduced with ambiguity, and yet these options only exist if the individual involved questions whether manipulation is occurring.

Manipulation is a complex topic on which knowledgeable persons, such as researchers and philosophers, do not agree. For philosophers it is a moral issue, while for researchers manipulation is embedded in all social situations between people, and the term may be used in a morally neutral manner. Others argue that all communication is persuasive and that manipulation is a form of persuasion, not meant to imply positive or negative morality; thus, the definition of manipulation is broadened dramatically. While this definition is a minority view, it is mentioned here to emphasize the complexity of understanding the concept of manipulation.

Furthermore, there are manipulative situations in which not all individuals involved are deceived, and yet they are still manipulated. For example, Jane wants to claim credit for work she did not do, so she asks Mary if she can join the team that performed the work after the majority of the work is complete. Mary denies Jane’s request. Jane responds by saying she will force Mary to make Jane a member of the team. Jane then goes to her uncle, the president of the company, and tells him about all the work she did and how she is not receiving due credit. The president lists Jane as a member of the team and publicly thanks her for all of her work and effort. Jane deceptively

manipulated the president and transparently manipulated Mary. The other team members are somewhere on a continuum from undeceived to deceived. Thus, not all forms of manipulation require that everyone manipulated is deceived.

Failed attempts at manipulation and/or overt manipulation (that is, when individuals are aware of the manipulation but have no recourse but to accept the situation) can result in resentment and suspicion of the manipulator; the victim may experience feelings of remorse, anger, fear, guilt, or shame. Interestingly enough, while coercion is one of the harsher forms of manipulation, the victim's response may differ. A victim may feel extreme levels of guilt and shame for allowing manipulative behavior, but when the manipulation becomes coercion (that is, by force), the victim may not feel the same level of responsibility or remorse.

Thus, there are different levels and types of manipulation, and not everyone agrees as to when a situation is manipulative. Individuals can and do idiosyncratically determine for themselves when they perceive manipulation and respond accordingly. But society also has boundaries which deem manipulative behavior unacceptable. Medical and psychological researchers list manipulation as a key characteristic in a variety of psychological diseases: borderline personality disorder, psychopathy, and antisocial personality disorder, to name a few. Criminal justice and business researchers frequently examine types of manipulative behavior that can lead to criminal charges; for example, the Securities and Exchange Commission (SEC) is a branch of government specifically charged with determining what level of stock market manipulation is illegal, such as spreading false rumors causing stock prices to change or ordering a vast number of shares without the intention of purchasing, leading others to think the stock is more viable than it is. Placing a stigmatized label, such as felon or mentally ill, on individuals who manipulate excessively or in a particular manner demarcates between what society will tolerate and what it will cease to countenance and attempt to hinder through penalties.

Finally, no account of manipulation would be complete without mentioning the times when manipulation is more likely. When individuals' choices are highly limited by the power of

others, it may be expected that the individuals will respond with manipulation. Incarcerated criminals, citizens under harsh and cruel regimes, and children raised with parenting styles that are highly restrictive, are but a few examples of these individuals. Situations that call forth a higher frequency of manipulation need further investigation; currently, these situations appear as asides to other studies with only infrequent mention in studies on manipulation.

Manipulation when used successfully goes unnoticed by those influenced by the manipulator. But when an individual becomes aware of manipulation and attributes the manipulator with self-serving motives, anger, shame, fear, and other emotions can occur. Thus, depending on the type of manipulation and the motives attributed to it, a manipulator may live with unexpected consequences from the individual he or she attempted to manipulate.

## Marketing, Deceptive

Deceptive marketing is a subset of deceptive business practices that occur, according to the U.S. Federal Trade Commission (FTC), when there is "a misrepresentation, omission, or practice that is likely to mislead the consumer acting reasonably

in the circumstances, to the consumer's detriment." Marketing deception is legally distinct from other forms of deception because it focuses on injury to the consumer as a result of the lie or deception, regardless of intent. In the United States and most countries with consumer protection laws, the specific meanings of "deceptive practices" and "injury" are not spelled out in statutory form. Rather, the legal interpretation of

Exploiting the public's concern over vitamin deficiency as America entered World War II, the Doughnut Corporation unsuccessfully sought the endorsement of the Nutrition Division of the War Food Administration for "Vitamin Donuts." The Food and Drug Administration, also skeptical of these types of claims, eventually developed a rational program for food enrichment.

marketing deception comes from case law and the principle of *stare decisis*, precedents from prior decisions that are adhered to in future legal cases.

Marketing is the subset of business practices that affect consumers directly through exchange between buyer and seller. Consumer value, or utility, is created when the exchange satisfies the consumer's wants and needs. Producer value, or profit, is derived from receiving compensation. Marketing consists of a mix of activities involving product, price, promotion, and distribution (place). While marketing deception is most often associated with advertising and promotion, other forms of material influence occur when a product does not perform as expected, prices are unfairly manipulated, or products are not available as represented. Marketing deception occurs when the producer or seller uses deceptive practices in any of these marketing activities in order to gain an unfair advantage over competitors or consumers.

In commercial exchange, the free flow of information is viewed as essential to helping the consumer know the prices and choose between products. Marketing deception must be legally defined because First Amendment rights have been extended by the courts to advertising and other forms of speech that promote commercial transactions. However, the U.S. Supreme Court has ruled that only truthful commercial speech is protected. False, misleading, or deceptive advertising or other forms of promotion are not protected by the law.

A consumer or buyer is considered to have been injured when a misrepresentation, omission, or deceptive practice is a material one. In the legal environment, material means that a consumer's actions or decisions are affected in ways that are different from what would have occurred had the consumer not been deceived. For example, aspirin is a specific pain-killing compound that is identical in all products called aspirin. If Brand A claims that its aspirin product is more effective than aspirin from Brand B, and consumers then choose Brand A because of this claim, a material deception has occurred.

Deceptive advertising can be explicitly false, or it may make misleading claims that are true but lead consumers into making false or incorrect inferences. Inferences of meaning are difficult to

regulate. There may be considerable doubt about what has occurred in the mind of an individual consumer and whether or not the implication has misled the consumer. Advertising or other sales presentations may use “puffery,” praising the product with vague and general subjective opinions, superlatives, or exaggerations but without stating specific facts. Legally, this is often treated as allowable exaggeration, the FTC position being that consumers expect inflated claims in advertising, recognize it, and do not believe it. The Uniform Commercial Code of 1996 upheld the right of advertisers to use puffery, placing the burden of proof that the buyer was misled on the buyer.

Individual ability to interpret implicating statements may also vary, leaving the question of how many consumers have to be misled in order to consider the implication deceptive. The FTC may prohibit a representation as deceptive or unfair if it implies something to a substantial portion of the population that is different from the material facts about the product. Both case law and evolving legislation have shifted from regulating literal statements, which are readily defined, to addressing implications that are misleading and injurious. The prescriptive nature of case law means that establishing when an implication is ambiguous, misleading, or materially false has resulted in few successful prosecutions.

### Legal Approach to Deceptive Marketing

The legal approach to marketing deception is rooted in protecting competition rather than consumerism. Through the 19th century and with the expansion of economic activity, legal systems favored commercial over individual interests and were lenient in treating advertising as matters of opinion. Prior to the rise of mass media, product claims were often outrageous but little was recorded that could be challenged. *Caveat emptor* (buyer beware) guided the consumer; the buyer was expected to be skeptical of claims, examine goods before purchasing, and make an informed decision.

Defining deceptive marketing evolved slowly. The Sherman Antitrust Act (1890) and Clayton Antitrust Act (1914) were among the earliest legislation to deal with unfair business practices. Both were intended to prevent anticompetitive

practices that would increase costs to the consumer. The Federal Trade Commission Act (1914) created the FTC to enforce the Clayton Antitrust Act and provided additional legal guidelines, including those against “deceptive acts or practices in or affecting commerce.” The act did not specifically address the use of false or misleading advertising. In 1922, the U.S. Supreme Court upheld an FTC interpretation that false advertising is a form of unfair competition. A subsequent ruling (1931) limited the ability of the FTC to protect consumers; the court determined false advertising could not be prohibited unless there was evidence of injury to a competitor.

The Wheeler-Lea Amendment (1938) to the FTC Act declared “unfair or deceptive acts or practices in commerce” unlawful and gave the FTC injunctive power over false advertising of food, drugs, cosmetics, and therapeutic devices when that advertising was deemed to cause injury to the public. The Lanham Act of 1947 (amended by the Trademark Revision Law of 1988) gave additional guidance about the scope of deception. Misrepresenting competitors’ products was also treated as deceptive marketing when claims materially damage the competitor through the loss of sales or goodwill. Injury to competition most often occurs in comparative advertising.

### Consumer Rights and Deceptive Marketing

In March 1962, President John F. Kennedy launched the era of consumerism with a speech to Congress outlining consumer rights. Legislation such as the Fair Packaging and Labeling Act (1966) and the Truth in Lending Act (1969) provided specific injunctions against deceptions directed to consumers. FTC authority expanded dramatically throughout the 1970s and focused on the issue of what constitutes unfair advertising. In 1972, the FTC Act was amended to extend its power to any product if false advertising represented a threat to public health and safety.

The terms *unfairness* and *deceptive* are undefined by the FTC Act. An FTC response to the U.S. Senate following passage of the FTC Improvement Act of 1980 clarified that consumer injury is the central issue in cases alleging unfairness. A three-part test was established for consumer injury: (1) the injury must be substantial, (2) it

must not be outweighed by countervailing benefits to consumers or competition, and (3) it must be an injury that consumers themselves could not reasonably have avoided. The third part of the test alludes to deception, such as the withholding of information (omission) or the misrepresentation of information needed to comparison shop or make purchase decisions.

A prescriptive definition of deception was created in October 1983, in a Policy Statement on Deception given to the U.S. House of Representatives by FTC Chairman James Miller III. The statement included three essential elements. First, the misrepresentation, omission, or practice must be likely to mislead the consumer. “Misrepresentation” means a statement is contrary to fact. “Omission” is the failure to disclose qualifying information that would prevent a practice, claim, representation, or reasonable belief from being misleading. “Practices” are seller’s actions; examples of misleading actions include applying false quality seals, bait-and-switch appeals, playing on consumer fears, or creating impressions that the consumer has won a prize or is getting something for free.

Second, the practice must be considered from the perspective of a reasonable consumer. The FTC considers who the message is targeting and takes into account factors such as age, education, intellect, and frame of mind. For example, advertising targeted to children will be evaluated differently from marketing appeals directed to typical adults. Third, the deception must have materiality. A material misrepresentation means the information or practice is important to consumers and will affect their choice or actions with regard to a purchase decision. If the deception would not cause a reasonable consumer to alter his or her purchase decision, the misrepresentation is not considered material. FTC-related legislation subsequent to the 1983 policy statement has focused on disclosure, substantiation, corrective advertising, and regulation and enforcement issues, but definitions of unfairness and deception have not significantly changed.

### Foreign Laws Regulating Deception

Laws prohibiting false advertising and marketing deception are found in many countries. For example, in the Australian Competition and Consumer

Act 2010, definitions are similar to those in the United States. The act states the following:

If the overall impression left by an advertisement, promotion, quotation, statement or other representation made by a business creates a misleading impression—such as to the price, value or the quality of any goods and services—then the conduct is likely to breach the law.

Australian law notes that deception may not be the same for all audiences, and it requires that deception must be material to be illegal. Explicitly in Australian law intent has no consequence; deception is judged by how business practices affect consumer thoughts and beliefs.

In China, conversely, the Advertisement Law adopted in 1995 is primarily instructive. The law states, “An advertisement shall be true to facts, lawful, and in compliance with the requirements of raising socialist cultural and ideological progress. An advertisement may not contain any false and deceiving information, and may not cheat or misguide consumers.” Advertisers are expected to “adhere to the principles of fairness and trustworthiness.”

## McCornack, Steven

Steven McCornack is one of the most cited deception researchers in the communication discipline, with over 1,100 citations of his work. His research career in deception began with his undergraduate thesis at the University of Washington. In this research, conducted under the supervision of Malcolm R. Parks, McCornack and Parks proposed the term *truth bias*, which is now one of the most researched and robust findings in the deception literature.

McCornack and Parks also put forward a model of Relational Deception. Included in the model was the examination of relational closeness, confidence in the ability to discern truth versus lies spoken by relational partners, truth bias, and accuracy of deception detection. With the model, they proposed that relational closeness or involvement with a partner led to increased confidence in one's ability to detect deception. As confidence increased, so, too, would truth bias. Truth bias was believed to have a negative effect on detection accuracy. So, as relational partners became more involved and relationships developed, ultimately the truth bias would increase, and partners would be less able to detect each other's deception. This model was tested by McCornack and Parks and

retested by McCornack and Timothy R. Levine, who found support for the model and that it also was generalizable across low, moderate, and high levels of aroused suspicion. A meta-analysis demonstrated further support for the model.

### Information Manipulation Theory

As McCornack began work on his Ph.D., he began collecting data from college students whom he asked to report on a lie told to a romantic partner. From this data he created scenarios with gender-neutral names like "Chris," and then asked research participants to write down what they thought they would say in response to the scenarios. He discovered violations of Paul Grice's maxims, or the cooperative principle, in the messages participants created. Thus, information manipulation theory (IMT) was born.

McCornack created IMT to better understand the deceptive messages that individuals create, and he posited that messages can be manipulated along dimensions of each of Grice's maxims. Thus, a message may vary in ambiguity (manner violation), how much relevant information it contains (relevance violation), in its veracity (how much false information it includes or quality violation), and in the amount of relevant information it contains (quantity violation). McCornack is clear, however, that the violations on which IMT is based are not to be used to create a typology, as any deceptive messages can vary along each of the four dimensions, and not just along one of the dimensions.

Much of the research on IMT has used the violations to understand perceptions of deception and how these perceptions influence perceived competence of deceptive messages. For example, messages that tend to contain more quality violations, or more complete dishonesty, have in some situations been found to be less competent than messages that do not contain as much distorted information. IMT, although disputed even by McCornack if it meets all the criteria necessary to be considered a theory, has proved to have strong heuristic power. It has stimulated much research, including comparing individualistic and collectivistic perceptions of messages, self-construal and locus of control and perceptions of deceptive messages, and the organizational situations and perceptions of deceptive messages in response to these situations.

Information manipulation theory 2 (IMT2) is a combination of the original IMT and McCornack's chapter on deceptive message production published in John O. Greene's *Message Production: Advances in Communication Theory*. IMT2 is a comprehensive theory which includes 15 propositions on deceptive message construction. Deception, according to IMT and IMT2, is the covert manipulation of information along the four dimensions that represent violations of Grice's maxims. McCornack adds to this in IMT2 by claiming that lying behavior may be easier at times than telling the truth, which changes much of what is believed about deception causing arousal and thus potential leakage cues. Also, lying may require memory retrieval and not the construction of new information to be used in a message. IMT2 adds to the deception literature in that it may challenge much of the previous research on message production, intention, and arousal theories.

### Aroused Suspicion

Aroused suspicion is another of McCornack's contributions to deception literature. In an effort to find out why previous researchers could not improve lie detection accuracy through induction of suspicion, he and colleagues proposed that a dichotomous (low and high) manipulation of suspicion may be the cause of the no or mixed results. To address this, McCornack and colleagues induced suspicion at three levels: low or no suspicion, moderate, and high levels of suspicion. They found a curvilinear relationship between romantic partners such that detection accuracy increased at moderate levels of suspicion but decreased at low or high levels of suspicion. Levine later retested this model with strangers and found a linear effect for suspicion in that it incrementally increased lie detection accuracy as suspicion increased; at the highest levels of induced suspicion, strangers were the most accurate at detecting lies.

McCornack also added to the aroused suspicion literature by explicating and testing two different types of suspicion—state and trait suspicion. State suspicion is the suspicion that would be induced in an experiment, and trait suspicion he called Generalized Communicative Suspicion (GCS). GCS is the predisposition of an individual to be suspicious; an individual may be more

inclined to be suspicious of all information. McCornack and colleagues found that individuals who were already highly suspicious (high level of GCS), and who received a moderate induction of suspicion, demonstrated a higher than average ability (70 percent) to accurately detect deception. They also found that GCS moderates the relationship between state suspicion and lie bias. Further, they found that women who had high levels of GCS had the strongest emotional reactions to discovered deception when compared to men. Tests of the GCS measure have demonstrated support for dimensionality, construct validity, and for predictive utility of the measure.

McCornack has also contributed to the deception literature by training individuals to detect deception, the probing effect, lie acceptability, discovered deception, and the veracity effect. His work in deception has evolved from the messages created to understanding the creation of deceptive messages, and his research is the foundation of much of the deception research in the communication discipline.

## McCornack-Parks Model

The McCornack-Parks Model is a model of deception detection conceptualized by communication scholars Steven McCornack and Malcolm R. Parks. Broadly described, the model posits that increases in relational intimacy lead to decreases in deception detection ability. However, the relationship between these variables is argued to be indirect, mediated by confidence in detection ability and truth bias.

The model derives from work McCornack conducted as a part of his senior honors thesis at the University of Washington, under the supervision of Parks. McCornack was interested in exploring the impact that increases in romantic intimacy had upon accuracy in deception detection. At that point in time (the early 1980s), only a handful of previous studies had explored the effects of intimacy upon accuracy—with mixed results. One line of research, authored by Randy Brandt and his colleagues, had investigated the detection abilities of strangers, manipulating “familiarity” through repeated exposure to the truthful behaviors of message sources. They found a curvilinear effect for such familiarity on detection accuracy, such that increases in the number of exposures to truthful source behavior increased accuracy in detecting deception to a certain point, after which additional exposures resulted in decreased accuracy.

Other scholars had examined actual relational partners, comparing accuracy across different types of involvements. Mark Comadena, for example, had studied the comparative detection accuracy of marital spouses versus friends, finding that spouses had higher accuracy. In contrast, Gerald Miller and his colleagues found little difference in detection accuracy between spouses, close friends, and strangers.

McCornack and Parks argued that one reason for the conflicting findings was that the

relationship between familiarity and accuracy was indirect, mediated by two variables. The first of these was confidence in detection ability. The second was a variable that would come to be widely studied and cited within the field of deception: a bias toward consistently perceiving a partner as truthful, that McCornack and Parks labeled “truth bias.”

McCornack and Parks concluded that these variables likely were causally interdependent. Specifically, they reasoned that increases in relational intimacy would lead partners to believe that they could, in fact, detect their partners’ lies (that is, confidence in detection ability). At the same time, this increase in confidence would be associated directly with an increased belief that their partners would never lie. McCornack and Parks argued that if individuals believe they can always catch their partners’ lies, they are more likely to process partners’ communication heuristically and presume associated positive beliefs, such as “my partner is always telling me the truth” (that is, truth bias).

Truth bias, in turn, should be directly negatively related to accuracy in detecting deception. That is, if people believe that their partners never lie, they will not detect their partners’ lies when they do occur. The practical implication of the proposed model, in toto, is that individuals involved in romantic relationships should believe that they can detect their partners’ lies, should believe that their partners would never lie to them, and should have decidedly low deception detection accuracy.

Using partial correlations, McCornack and Parks tested this causal string in data they collected from 60 romantically involved college dating couples. Their results confirmed their proposed model. A conference paper based on their results subsequently won Top Paper in the Interpersonal Division of the International Communication Association and was published the following year in *Communication Yearbook* 9.

In 1990, McCornack and Timothy R. Levine replicated the McCornack-Parks study within a larger sample, using path analysis to test the causal model. The McCornack-Parks Model provided the best fit to their data. Subsequently, psychologist Bella DePaulo and her colleagues conducted a meta-analysis of studies examining

confidence and detection accuracy. As a part of their meta-analysis, they tested the McCornack-Parks Model, finding strong support for the proposed causal string. Thus, the McCornack-Parks model appears to be robust.

## Medical and Pharmaceutical Industry

The medicine and pharmaceutical industry is one of the most lucrative businesses in the United States. In 2010, approximately \$2.6 trillion was spent on health care, or \$8,402 per person. As the average consumer pays only about 6 percent of their income on health care, the federal government assumes a large share of the cost. In 2010, half of U.S. government revenues were spent on health care. Of this amount, 12 percent was paid by individuals, and insurance, both public and private, paid the remainder. With this much money invested in health care, it is not surprising that there are many opportunities for deception and fraud.

In an effort to prevent deceptive and fraudulent behaviors, expectations, or codes of conduct, for the behavior of medical professionals as well as pharmaceutical companies have been developed. The American Medical Association states in its Code of Ethics that "A physician shall uphold the standards of professionalism, be honest in all professional interactions, and strive to report physicians deficient in character or competence, or engaging in fraud or deception, to appropriate entities."

The Pharmaceutical Research and Manufacturers of America (PhRMA), which represents the leading pharmaceutical and biotechnology companies in the United States, also has a code of conduct created as a means of self-regulating the industry. The code states that when a pharmaceutical representative speaks with a health care professional they must act as follows: Promotional materials provided to health care professionals by or on behalf of a company should: (1) be accurate and not misleading, (2) make claims about a product only when properly substantiated, (3) reflect the balance between risks and benefits, and (4) be consistent with all other Food and Drug Administration (FDA) requirements governing such communications.

### Deception by Pharmaceutical Companies

Although there are codes of conduct and expectations of ethical behavior, there are many examples of deceptive and unethical behavior by

pharmaceutical companies. One area in which pharmaceutical companies deceive physicians and other health care professionals is through sponsored clinical trials. For example, in 2008, the *New England Journal of Medicine* published a review of antidepressant efficacy studies. Of the studies examined in the review, 38 had positive results, and most of these had been published. The remainder showed negative results. Of those with negative findings, 22 had not been published and 11 had been published to seem as though the results were positive. Only three of the studies with negative results were accurately reported in medical journals.

Another method of deception utilized by pharmaceutical companies are seeding trials. Seeding trials are clinical experiments supported by pharmaceutical companies that include multiple centers and physicians. Seeding trials take place after a new product has been introduced and appear to represent a scientific trial of the new medicine. Instead, however, they are a marketing effort to encourage physicians to try the new product and become accustomed to prescribing it to patients.

In the past, pharmaceutical companies used Continuing Medical Education (CME) programs as marketing tools and were able to send physicians on resort excursions where they could have discussions with other physicians and attend programs about the drugs being promoted by the company. These vacations, and expensive meals for physicians and other health care professionals, have been curtailed to some extent, and now CME programs are expected to focus on disease states and not on pharmaceutical products. In addition, the money that pharmaceutical companies spend on physicians has to be reasonable, not part of a recreational or entertainment event, and company activities must be appropriately conducted so as to promote professional and/or informational communication. Pharmaceutical sales representatives, once called detail representatives or detail people, may now spend less money on meals or entertainment for physicians, but their companies have compensated for this by employing overlapping sales forces and multiple companies marketing the same product. These tactics are used to inundate physicians with information and reminders about pharmaceutical products.

*An X-ray from a medical case report published in October 2008 shows a bottle fragment that a patient claimed was broken off in his body cavity during an assault; doctors discovered that he had secretly inserted it himself. Munchausen syndrome, which is the pretense of having a serious illness, was diagnosed in this case. It is one way that patients attempt to deceive physicians.*

Another method of deception is the promotion of off-label uses of pharmaceutical products. The Food and Drug Administration approves medicines for specific treatments, dosages, and other criteria based on laboratory and clinical trials; off-label uses occur when drugs are prescribed for conditions, patients, and in ways that have not been FDA-approved. Physicians are allowed to use their knowledge and experience to determine when it is appropriate to use a medicine for an off-label purpose. Pharmaceutical sales representatives and companies, however, are not allowed to market these uses. There is a temptation to do so, however, because it is expensive and time-consuming for companies to complete the testing necessary to obtain FDA approval for multiple

uses of a product. Thus, a drug company may strive for one or more approved uses, and then talk to physicians about unapproved uses of the medicine.

### **Deception Aimed at Consumers**

Pharmaceutical companies also misrepresent information to consumers or patients. One method for doing this is through video news releases about products. These video news releases look like a regular news program or news story, yet they are carefully created by pharmaceutical companies to look this way. They can range from straightforward information communicated by a seeming "journalist" to being highly sophisticated in their delivery of information, such that news agencies can insert their own reporters asking scripted questions and then presumably have these questions "answered" by the video of an expert responding to the question.

Another method of consumer deception is direct-to-consumer advertising on television and other media. At times this can be extreme, such as when Ortho Pharmaceutical Corporation marketed Retin-A, an acne medication, for the reduction of wrinkles and skin discolorations. Retin-A, however, was not approved for the treatment of wrinkles and skin discolorations. In an effort to hide their marketing of this unapproved use of their product, employees of Ortho Pharmaceutical shredded documents and destroyed videotapes. However, papers detailing their efforts still existed and were subpoenaed, uncovering the fraudulent marketing program.

### **Deception by Health Care Professionals**

Not only are physicians and patients deceived, but there also are times when health care professionals, including physicians, may themselves feel pressure or an obligation to lie. When a patient is terminally ill, physicians often struggle with telling the patient that he or she has little time left. In fact, research shows that physicians consistently overestimate how much time patients have until they will die, and this propensity increases the closer they are to the patient. When patients are asked, however, if they want the complete truth, the majority of them report that they do. They want the opportunity to understand what is happening to them, and without this knowledge their

degrading health and lack of understanding can create more anxiety for the patients, not less.

Physicians and other health care professionals may also be willing to use deception when dealing with insurance companies or third-party payers. Health care fraud through incorrect, or deceptive, billing is a pervasive practice. Another method of deception is called "gaming," which occurs when health care professionals deceptively persuade third-party payers to pay for patients' care.

The introduction of the Internet created still more methods of deception. One technique is the use of "spamnals," which appear to be legitimate online scientific journals. Spamnals invite physicians to submit articles, which the online journals publish after the physician or scientist pays the journal a small fee. There are many legitimate journals with true peer review, but spamnals are not legitimate and may publish poorly conducted research, which may then be misleading to physicians, patients, and other health care professionals.

Even legitimate journals may publish work that is later retracted for inaccuracies or other issues. It would seem that this would happen randomly, but this is not always the case. In an analysis of retracted medical and scientific articles, R. Grant Steen found that, "Retractions tend to appear in journals with an impact factor significantly above average . . . (they) are also significantly clustered in a specific subset of journals and are written by a specific subset of 'repeat offenders.'"

### **Patient Deception**

Finally, even patients lie. Munchausen syndrome, or the pretense of having a serious disease or of having a disease by proxy, as when parents make their children appear to have serious illnesses, is an example of how patients may effectively deceive physicians in order to receive health care services they do not need. With experience it would seem that physicians would become better at detecting deception when, in fact, they are not. Research that investigated physicians' ability to tell when they were treating actors and not real patients found that physicians were relatively unable to determine when they were treating an actor instead of an actual patient.

## Memoirs

A memoir is a category of autobiography that focuses on an author's experience rather than his or her entire life. They have been a challenge for literary critics for centuries because memoirs can push the boundaries of literary truth and deception. Many memoirs have been revealed to contain only partial truths, and in some cases, little truth at all. The controversial nature of truth in memoirs has prompted critics to propose another genre for memoirs: creative nonfiction.

Memoirs are a type of autobiographical writing, distinct from autobiography in the scope of experience. The word *memoir* is derived from the French word *mémoire*, which translates to memory or reminiscence. While the words *autobiography* and *memoir* are used almost interchangeably in the marketing of books, autobiographies tend to focus on an author's entire life, with attention to chronological order and verifiable facts. Memoirs, on the other hand, have a much narrower scope and focus on specific, transformative moments in an author's life.

*Confessions*, written in 371 C.E. by Saint Augustine, was one of the first recorded memoirs. The book describes Augustine's theft of a few pears and its effect on his transformation from a larcenous, promiscuous teenager into a faith-driven adult. Xenophon's *Anabasis*, written in the 4th century B.C.E., prior to Saint Augustine's memoir, recounts how he and his troops managed to make their way back to safety after getting trapped behind enemy lines. Earlier memoirs likely exist, but written records are sparse around this time period. These early autobiographical examples are distinctively memoirs, as they focus on pivotal, transcendent, or spiritual experiences that subsequently develop the central character's personality, beliefs, or eventual lifestyles.

Because memoirs are experiences written from memory—which can be fallible—literary critics

have argued whether memoirs with false information are actually deceptive or simply erroneous and whether they should still be classified as nonfiction works. A common definition of deception is the act of deliberately misleading another without permission to do so. Under this definition, memoirs may not be deceptive, as the authors are unintentionally misremembering details and not deliberately misleading readers. However, other definitions emphasize that any falsehood that benefits the communicator is deceptive. Under this definition memoirs with unintentionally exaggerated or misrepresented facts may be deceptive.

### Hoaxes of 2003

The authenticity of memoirs has come under substantial scrutiny and fact-checking, and some of these investigations have revealed memoirs that are deceptive regardless of the definition. In 2003, three memoir hoaxes were unveiled roughly around the same time, sometimes referred to as a Triple Crown of hoaxes. The most notable of these was the James Frey scandal. Frey published a memoir titled *A Million Little Pieces* (2003), in which a 23-year-old man overcomes drug addiction and alcohol abuse through treatment and willpower. The book was featured in Oprah Winfrey's book club and acclaimed by Winfrey to be "like nothing you've ever read before." However, problems with core elements of Frey's story were uncovered, including the fact that he had not actually lived a life of illicit drug use. Winfrey invited Frey back on her show with Nan A. Talese, the head of the Doubleday publishing company, to publicly scold Frey for his fraud and Talese for her failure to promote honesty and truth in publishing.

Another hoax unveiled in 2003 involved an entirely constructed identity and life story. J. T. LeRoy, author of *Sarah* (1999), *The Heart Is Deceitful Above All Things* (1999), *Harold's End* (2005), and *Labour* (2007), covered LeRoy's life of drug addiction, sexual and physical abuse, prostitution, and vagrancy. LeRoy's stories developed a cult following until 2003 when LeRoy's identity was revealed as a fabrication created by author Laura Victoria Albert. She kept LeRoy's identity secret by claiming he had extreme shyness and issued statements saying he had insecurities about being a transgendered author. Eventually,

Albert's partner, Geoffrey Knoop, revealed that LeRoy was a literary hoax. In 2007, Albert was convicted of fraud because she signed legal documents with her fictional character's name.

The third 2003 hoax involved the popular author Nasdijj, pen name of Timothy Patrick Barus, who published three "memoirs": *The Blood Runs Like a River Through My Dreams* (2000), *The Boy and the Dog Are Sleeping* (2003), and *Geronimo's Bones: A Memoir of My Brother and Me* (2004). Nasdijj claimed to be Navajo with two adopted sons, one who had fetal alcohol syndrome (FAS) and another who was human immunodeficiency virus (HIV) positive. He also claimed that "Nasdijj" was the Navajo word for "to become again," but according to Ivan Morris, professor of Navajo studies at Dine College, no such word exists in the Navajo language. Nasdijj's essay "The Blood Runs Like a River Through My Dreams" detailed his son's death induced by FAS, for which Nasdijj was a finalist in the National Magazine Awards. His identity was questioned when Nasdijj was accused of plagiarizing other Native American authors. When Morris was asked to review his book, he uncovered many discrepancies with facts and suspected Nasdijj was actually an imposter.

### Use of Deception

Some authors claimed to use deception to make a point. The memoir *Love and Consequences: A Memoir of Hope and Survival* (2008) was written by Margaret Seltzer under the name of Margaret B. Jones. Seltzer claimed to be half-Native American and wrote about life as a foster child adopted by African American parents and as a Bloods gang member. Seltzer was discovered to actually be fully white, with no Native American ancestry; she also had grown up with her biological parents and attended an affluent Episcopalian school in Hollywood. Seltzer later apologized, saying she sought to "give a voice to the voiceless." Some African American literature critics saw this as an embarrassment to the genre rather than an inspirational piece. Her book is still being published and is selling, despite the falsehood.

Some memoirs are partially true but still problematic. Herman Rosenblat, an actual Holocaust survivor, wrote *Angel at the Fence: The True Story of a Love That Survived* (2009). Rosenblat's memoir focused on his interaction, separation,

reunion, and marriage with a girl who passed him food through a fence while he was imprisoned at Schlieben, part of the Buchenwald concentration camp. Before being exposed as a fabrication, the film rights to the book were purchased for \$25 million. Winfrey described it as the single greatest love story she had heard in 22 years of the *Oprah Winfrey Show*. Literary critics, however, questioned the plausibility of the story's serendipitous plot. Rosenblat had, in fact, been imprisoned at Schlieben, but studies at Michigan State University revealed that neither prisoners nor civilians could have safely approached the perimeter fence at Schlieben. Evidence also arose that Mrs. Rosenblat and her family hid as Christians at a farm near Breslau, 210 miles away from Schlieben. Rosenblat ultimately admitted to fabricating the story, and Berkeley Books eventually dropped the book from publication.

Other authors claim that fabrications are a result of delusion or self-deception, in which they convinced themselves to believe what is false as true. In *Misha: A Mémoire of the Holocaust Years* (1997), Misha Defonseca, pseudonym of Monique De Wael, claimed to be a Jewish Holocaust survivor who parted with her parents when she was 8 years old. Her story chronicles a five-year, 1,900-mile walk across Europe, where she spent time in the Warsaw Ghetto, lived with wolves, and killed a rapist German soldier in self-defense. In actuality, she wasn't Jewish, didn't live with wolves, and never walked across Europe. However, Nazis had, in fact, taken her parents away when she was 4 years old. In 2008, 11 years after the book's publication, evidence was unearthed indicating that she was Catholic and attending school in Brussels when her story supposedly occurred. Defonseca confessed in a statement that said, "Ever since I can remember, I felt Jewish . . . I find it difficult to differentiate between reality and my inner world." Her delusion of what is real and what is not may not count as intentionally deceptive; however, her facts were incorrect and she admitted the fault in her actions.

### Creative Nonfiction

The questionable factual basis of memoirs has spawned debate about the legitimacy of "creative nonfiction" as a new genre. Edmund White, a novelist, essayist, and memoirist, argues that "a

writer's contract with the reader in a memoir is to tell the truth and nothing but the truth," whereas a novelist has made clear his intention to write fiction. White dislikes the phrase "creative nonfiction" because it sounds like a synonym for lying. Alternatively, author Melanie McGrath states:

Some of the facts have slipped through the holes . . . I have reimagined scenes or reconstructed events in a way I believe reflects the essence of the scene or the event in the minds and hearts of the people who lived through it . . . To my mind this literary tinkering does not alter the more profound truth of the story.

Despite conflicting beliefs on the genre's legitimacy, creative nonfiction has developed a loyal following of readers who believe in it as "artfully executed nonfiction." This new genre and attraction to memoirs as a whole have drawn more scrutiny to nonfiction, encouraging more thorough critiques and the pursuit for higher quality nonfiction as a whole.

Memoirs have been a literary anomaly since their inception in ancient history. They skirt on the edge of truth and deception. With countless examples of literary fraud and literary success, the memoir has exposed potential need for thorough analysis and critique and encouraged the growth of a new genre of literature altogether. Whether it will evolve into this new genre or continue as a subclass of autobiography is debatable, but it certainly is the basis for a cultural phenomenon in literature.

## Memory

Memory is essential to human survival. It contains the entirety of people's knowledge and understanding of themselves and their world. It helps individuals identify the objects around them, predict and understand events they may confront, and strategically interact with their physical and social worlds to survive and achieve their goals. It tells individuals where they have been, what they have experienced, and therefore who they are; what they can and cannot accomplish, what they should try and what they should not, and if they do try, how to go about it. Despite these essential functions of memory, and their overall success, memory can nevertheless be deceptive in ways great and small. It can simply fail, forgetting aspects of experience ranging from minor details to large segments of individuals' lives. And it can deceive, leading people to misremember events that did occur and even to falsely remember events that never occurred, sometimes very dramatic events such as being abducted by aliens or ritually abused in satanic cults.

Many people underestimate these multiple failures and deceptive functions of memory. Some even believe that memory works like a video camera, that it records exactly what is there to be perceived, that this recording remains unchanged in memory over time, and that it can be retrieved and recounted accurately. But nothing could be farther from the truth. Some aspects of what people experience are not stored at all. Memory misrepresents other aspects partially or completely; and it commits these deceptions during each of the three major stages of memory: encoding, storage, and retrieval.

### Processing and Encoding

When individuals first perceive and experience an event, their memories encode and store both more and less (and sometimes something different) than what they have experienced. Even though their eyes allow a relatively wide view of a scene, most of what is available to their eyes will not be noticed. Memory follows the focus of attention. Because attention is selective and cannot simultaneously focus on everything in people's sensory fields, memory is also selective, encoding only a fraction of what is available for processing.

Among the most interesting illustrations of this selectivity in processing is research on "change blindness." This work shows that very dramatic and large changes in people's visual field can take place as they watch something happen, though many fail to notice. Daniel Simons and Daniel Levin have provided many surprising illustrations of this phenomenon. In one striking demonstration, for example, research participants are talking with one person, are very briefly interrupted, and then many fail to notice when that person is replaced by a completely different person who continues the conversation as if nothing (and no one) had changed. Such failures occur, at least in part, because participants are not attending to specific features of the two persons necessary to tell them apart. Rather, people encode only broad categorical information, such as "a roughly 30-year-old white man." This phenomenon illustrates a broad category of failures of processing because of "inattention blindness," in which failures of attention translate to failures of encoding.

If something is attended to and encoded, it can nevertheless be encoded incorrectly. The act of encoding includes interpretation. Individuals encode a combination of sensory input and semantic (interpreted) meaning of an event, leaving memory traces that hold verbal meaning, sensory images, and affective traces of the emotions an experience evoked. These largely verbal stories people tell themselves about what happened and the feelings associated with them remain clearer over time than the sensory images and tend to become the primary basis of reported memories of the event. Because interpretation is a subjective process, and because it is central to

individuals' understanding of what happened and how they feel about it, what is encoded into memory can be strongly affected by individuals' existing knowledge, expectations, goals, and motivations, and by aspects of the context in which events unfold.

Most often, existing knowledge is helpful, telling people what they are seeing, what to expect from it, and what to do about it. To categorize a large, shaggy, onrushing figure as a "bear," for example, people must have learned the word *bear* and what it means; to decide to run away from the bear, people must have learned what bears might do to them. But sometimes people are led astray. Motivations can lead them to see what they want to see, such as when a male on a date with a beautiful woman "sees" her behavior as flirting when she only means it to be friendly. In addition, expectations can lead people to see what they expect.

A series of dramatic illustrations of disastrous expectation-based errors in encoding was provided by a line of research on the phenomenon of "weapons false alarm." This research was inspired by the case of a young black man, Amadou Diallo, who was shot to death by police officers who misperceived the wallet in his hand as a weapon. Researchers believed that Diallo's death, and those of other weaponless young black men shot by police, may not have been ill-intentioned. Rather, they suggested that cultural stereotypes associate blacks with violence, particularly young male blacks. Expectations based on these stereotypes can lead officers to mistakenly interpret neutral objects in the hands of young black males as weapons, particularly when officers feel endangered themselves, become focused on the detection and elimination of threats, and operate under pressure to react quickly, without time for reflection. A series of studies showed that neutral objects are more likely to be misinterpreted and reacted to as weapons in the hands of black men than white men, particularly when one must react quickly.

Memory researchers have documented a wide range of other effects comparable to the "weapons false alarm." People encode objective reality subjectively, colored through the lenses of pre-existing knowledge, expectations, emotions, and motivations triggered by their own personal

learning histories and personalities, and by the immediate context in which events occur.

### Characteristics and Components of Memory

Whether individuals encode correctly or incorrectly, memory is not constant. It fades over time, quickly at first, and then more and more slowly as time passes. As the original memories fade, they can morph and change. New events and sensory images blend, become confused with, or overwrite, the older experiences, and the old memories can become partially or fully reconstructed to fit more closely with people's current experiences, expectations, motivations, and beliefs.

To understand how this happens, it is important to consider what a memory is. As noted earlier, many think of a memory in terms of sensory images that can be replayed in their minds. Memory scientists, however, suggest that memory consists of three components: (1) beliefs about what did happen (the verbal stories referenced earlier), (2) sensory images, and (3) other relevant knowledge affecting the plausibility of what an individual believes happened versus that of alternative versions of what happened. Each of these can change over time, causing changes in what the person "remembers."

### False Memories

One line of research begun by Elizabeth Loftus illustrates the role that changes in these three aspects of memory can play in creating rich and detailed false memories for autobiographical events that never actually happened. Participants in these studies are first told by trusted family members that an event occurred earlier in their lives, even though the participant initially reported no memory of the event and did not believe it had happened. This led many participants to believe falsely that the event must have happened, even though they couldn't remember it. Participants were then told to spend time thinking about the event, trying to picture and remember it over the next week. The process of actively imagining and picturing the event creates images the person would not otherwise have. When participants returned to the laboratory the next week, some of them had developed false memories for the events, and they reported elaborate details of

what happened. The new beliefs and images created by the experimental procedures led them to develop new “memories.”

These rich, false memories developed for a variety of events, such as being lost in a mall as a young child, riding in hot air balloons, being attacked and bitten by vicious animals, nearly drowning and being rescued by a lifeguard, and others. False memories for some events were more difficult to implant, such as witnessing a demon possession. However, if participants were first given information enhancing the plausibility that demon possessions do occur, it became easier to implant false memories that they had witnessed such a possession themselves.

Though these studies illustrated how new, relevant information, images, or beliefs can facilitate the creation of completely false memories, related processes can more subtly alter memories for real events. Some internal motivations and goals seem to pervasively shape memories over time. These include the need for individuals to maintain self-esteem, to maintain coherent views of themselves, to justify their past actions, and generally to feel good. Other changes in memory are caused by external influences, such as conversations with others, or new information that causes individuals to think about the event from a different perspective. Among the most important external influences are those that occur when people are questioned about their memories. Suggestive questions can either directly state (“Did you see how drunk he was?”) or imply (“Did you see ‘the’ stop sign?”) that a particular version of events is true. These questions convey what others seem to believe happened and thereby affect individuals’ own beliefs (and through that pathway, their memories).

Despite the many ways in which our memories deceive people, individuals are largely unaware of these deceptions. Though they can knowingly lie, they are perhaps most often “honest liars,” reporting events as they remember them but failing to recognize how the normal processes of memory have misrepresented or fabricated the events they recount.

Ironically, the very conviction with which individuals hold their false memories may help them to deceive others. Evolutionary biologist Robert Trivers has recently argued that people’s many self-deceptions help them to deceive others and in

doing so also help them to survive, to get ahead, and to procreate.

## Men

Edel Ennis and colleagues define lying as a message that one gives to another by which they are deliberately deceiving them. Current research on the prevalence of lying in the United States is inconclusive. One school of thought proposes that lying is natural to the human condition. In this sense, lying is thought of as a frequent and fundamental part of everyday life. Others view lying and deceptive behavior in general as a threat to the moral fabric of society. Societies potentially

rise and fall on the success or failure of many to adhere to a set of real or perceived moral codes. Researchers continue in their efforts to verify the reality of these and other defining characteristics of lying.

Research indicates that 91 percent of the human population tells lies on a regular basis, and that many individuals engage in at least 13 major lies within any given week. People in these situations don't want to lie, but sometimes they are caught up in situations in which lying is the better choice of two evils. The following examples are common situations in which many individuals have engaged in lying:

A wife asks her husband to comment on her new hairdo. While in truth he may think it hideous, to keep the peace and remain in her good graces, he tells her, "It looks great, honey."

A child has a starring singing role in the school play. Her parents see that the child is excited and that she puts much effort into her preparation for the big event. However, while listening to their daughter rehearse her song, her parents comes to the startling realization that the child can't carry a tune. The parents are faced with a difficult choice: hurt the child's feeling by telling her she can't sing, or continue to offer encouragement by telling a little white lie. "Oh baby, you sound great. You're going to be a hit," the parents reply.

A homeless individual approaches a man on the street, asking if he has some change to spare. The man is faced with a mild dilemma. He knows he has some change in his pocket; however, he hesitates. For whatever reason, he doesn't want to give the homeless person money. He is forced to choose from his three options: keep walking, tell the homeless person the truth, or lie, saying, "Sorry, I don't have any money on me today."

In this sense, lying and deception appear to be normal to the human condition, which raises the question: Do men lie more than women? To many, this question is irrelevant; everyone lies, so what is the distinction between men and women who knowingly or unknowingly practice the art of self-deception? Yet, a growing body of research suggests that men lie more than women.

### Lies Men Tell Women

According to a study by sociologist Dina Graham Scott, men tell lies that vary from the mundane to

the elaborate and range from the easily detected to the truly creative, with the more creative lies taking a little more time to interpret. The problem is that men don't seem to learn which lies are successful and which lies are unsuccessful.

For example, there are the lies that men tell women in an attempt to have sex with them. Many women have been told, "You are so hot," by a man in his attempt to pressure her into having sex with him. His motive for lying is that she will be flattered if he tells her that she is beautiful. If he presumes that all women like to be flattered, lying to her should accomplish the goal. Whether this lie is successful or not, many men will lie and brag that he "scored" with the woman. Alternatively, he may also denigrate her in an attempt to distance himself from the failure of his lie to be successful.

The fake marriage proposal is a grandiose lie designed to leverage what a man interprets as a woman's desperation to get married and have children. Many men are aware that women have been socialized from a young age to believe that they are expected to become wives and mothers. To many women, it is difficult to imagine their lives manifesting anywhere outside of this matrix, thus constituting the perfect setup for the lie: "I really want to marry you and have children with you." The lie becomes extended when the man is already married, as he attempts to hide the ring line on his left hand. If the woman is savvy enough to ask if he is married, his response will be, "No, of course I'm not married," thus distancing himself from his wife, and possibly his children, whom he has also drawn into his lie.

The most critical lie men tell women relates to the potential for physical consequences in the form of disease and/or pregnancy in woman and girls. Many women have heard this line: "I've been tested, and I'm clean." Or, "You can't get pregnant, I've had a vasectomy." The motive for this lie, one of the most insidious that men tell women when begging for sex, emerges in the man's belief that women, especially younger women, are so unintelligent that he can coerce them to have sex. By telling this lie, the man abdicates all moral or ethical responsibility for the woman's life or safety. His intent is to use her for his own sexual pleasure; therefore, any concern that he might

transmit a venereal disease or impregnate her is anathema to his cause, which is to “love them and leave them” without taking responsibility for the outcome of his actions.

### **Lies Men Tell Men**

Research also indicates that men lie to other men as well. Some men are so accustomed to lying to other men that it seems natural to also lie to women. When men congregate in social areas, such as bars and around the office water cooler, their socialization includes lying about a variety of subjects. The male experience in war is a striking example of the lies men tell one another. Although one's participation in a war warrants others' admiration, some men will exaggerate their own experiences, particularly in combat, in an attempt to appear more powerful and invincible than other men.

Furthermore, the level of income, the type of cars they drive, a swinging lifestyle, and any assortment of status-related events serve to bolster men's own status over other men. The caveat is that many men will go along with the lie, which directs attention to the unwritten rule that some men appear to share: “I won't call you on your lies if you don't call me on mine.” While the social and psychological motivation for such deception varies, lies of this type may mask the stress many men face in the workplace, at home, and in the world of men in general. Men traditionally work and play within the highest environs of power constituting the institutions of business, politics, and religion. This is a world in which the little white lie has little meaning or currency. On the contrary, this is a world where lying and deception are considered mechanisms and instruments of success.

### **Types of Male Liars**

Research points to a model representing five types of men practicing the art of self-deception at this level. First, there is the man of absolute integrity who demonstrates a high sense of ethics and rarely lies. In his life, integrity is cast as the opposite of hypocrisy, which implies that people who lie and deceive others should account for their actions. Second, the real straight shooter is an occasional, flexible liar, a man who is truthful most of the time. He seldom lies, but when

he does he is subject to feeling remorseful and guilty. He is also quick to seek forgiveness from the people he lied to.

The model of absolute integrity and the real straight shooter both appear to represent men who maintain some sense of ethics regarding their business practices and relationships with people in the world around them. For example, Warren Buffet, the primary shareholder, chairman, and chief executive officer of Berkshire Hathaway, is ranked one of the world's wealthiest people. Some believe the stereotype that a man of this stature would have lied and cheated his way to the top of the business world. Yet the record shows Buffet to be a man of integrity and a real straight shooter when it comes to business practices. He is noted for a philosophy of personal frugality and will more than likely go down in history as a notable philanthropist, having pledged to give away 99 percent of his vast fortune to charity and other philanthropic causes.

Third, the pragmatic liar lies when the situation calls for it. This man lies when he feels it is in his best interest. This is also a man who represents himself as ethical at every turn, always talking about morality. However, as people learn more about him, they find that his ethics go only so far. This is a man who talks of family values and then cheats with other woman. He may also be a man who commits acts of incest and domestic violence.

The model of the pragmatic liar stands in stark contrast to the standards established by the man of absolute integrity and the real straight shooter. The pragmatic liar is the hypocrite who has very little or no inclination to account for his actions unless forced to the task of confession. Jimmy Swaggart is one such embodiment of the pragmatic liar. Swaggart was a well-known Pentecostal pastor and televangelist hosting a weekly broadcast televised around the world to 3,000 stations and cable systems. He preached the Gospel, railed against homosexuals, and cast himself as the standard for moral purity and godliness. At least that's what he wanted everyone to believe. In 1988, however, he was implicated in a sex scandal involving a prostitute and was initially suspended, defrocked, and removed from the ministry. The hypocrisy and lies rose to a crescendo during the process, demonstrated by his infamous “I Have

Sinned” speech, in which he asked God to forgive him and forget about his sins. Three years later, he was arrested a second time for solicitation of a prostitute. Instead of perpetuating the lie of forgiveness for a second time, he simply told church authorities that “The Lord told me it’s flat none of your business.”

Fourth, the Pinocchio liar is someone who exaggerates often and has no qualms about lying, particularly if he wants something from another person. Pinocchio, a fictional character developed

*Lies that men tell women include those that are motivated by a desire to have sex. If a man presumes that all women like to be flattered, lying to her with “you are so hot,” should accomplish his goal; if not, he may lie to his friends that he “scored” anyway.*

by Italian writer Carlo Collodi in 1883, is a wooden boy who is prone to telling lies and fabricating stories, in which case his nose grows longer. Therefore, the Pinocchio liar in this sense serves as a metaphor for a man who lies so much that his nose is said to be visibly growing before others’ eyes.

Political history points to several individuals who may fit this description. One example is former president Bill Clinton, who lied under oath about his relationship with intern Monica Lewinsky. In 1998, he became the second president in U.S. history (the first was Andrew Johnson) to be impeached by the House of Representatives. President Richard Nixon barely escaped impeachment for lying about his involvement in illegal activities, including wiretapping and harassment of political opponents in the Watergate scandal in the 1970s. Nixon tried to cover up the misdeeds, but the truth eventually came to light and he was forced to resign. In addition, George W. Bush, the 44th U.S. president, was accused of lying about weapons of mass destruction, terrorist training camps, and a connection between Saddam Hussein and Al Qaeda, which sent the United States into a war with Iraq.

Finally, the compulsive liar simply cannot tell the truth about anything. This man lies even when it is not necessary for him to do so. This is a rather dangerous person to confront, particularly because he will exhibit a personality that reflects a specific type of pathology. For the compulsive liar, lying is a routine event. Like any addiction, it is difficult to recognize or stop. Compulsive lying is symptomatic of a larger problem such as extreme narcissism and borderline personality disorder.

Tour de France record holder Lance Armstrong epitomizes the compulsive liar. Heralded as probably the greatest cyclist in American history, Armstrong was seen as a philanthropist and founder of the Livestrong Foundation, which provided support for cancer patients. While his public image was that of the golden boy, his private life now appears full of dark secrets. For example, he announced his retirement from competitive cycling while facing a federal investigation into doping allegations. He was ultimately charged with having used illicit performance-enhancing drugs. Officials concluded that Armstrong

undertook what is said to be “the most sophisticated, professionalized, and successful doping program that the sport has ever seen.” Nevertheless, he lied continuously, denying the charges at every turn and going so far as to threaten and sue individuals, teammates included, who came forward to substantiate the charges. After years of public denial and public pressure to come clean, Armstrong appeared in a television interview conducted by Oprah Winfrey, where he admitted to doping.

### Conclusion

The question of the efficacy of men lying more than women has some merit in examination. As there is no conclusive argument, more research into the subject of lying and deception in gender roles is necessary.

## Mental Effort in Lying

There are many reasons why lying often requires more mental effort than truth-telling, particularly in an interview setting, and various sources provide empirical evidence that lying is indeed cognitively more demanding. If the reasons why lying requires mental effort are known, it is possible to predict under which circumstances lying is mentally taxing.

In an interview setting there are many factors that contribute to a liar’s cognitive load. First, formulating the lie itself is cognitively taxing. Liars need to make up their stories while monitoring their fabrications so that they are plausible and adhere to everything the observer knows or might find out. In addition, liars must remember their earlier statements, and know what they told to whom, so that they can be consistent when retelling their story. Liars should also avoid making slips of the tongue, and should refrain from providing new leads to investigators.

Second, liars are typically less likely than truth-tellers to take their credibility for granted. There are at least two reasons for this. The stakes (that is, negative consequences of getting caught and positive consequences of getting away with the lie) are often higher for liars than for truth-tellers. Smugglers are probably keener to make an honest impression on customs officers than nonsmugglers because the negative consequences for having to open their suitcases are much higher for smugglers than for nonsmugglers. In addition, truth-tellers typically assume that their innocence shines through, which could be explained by the illusion of transparency, the belief that “one’s inner feelings will manifest themselves on the outside,” and belief in a just world, the belief that people “will get what they deserve, and deserve what they get.” As such, liars will be more inclined than truth-tellers to monitor and control their demeanor so that they will appear honest to the lie detector.

Monitoring and controlling behavior is cognitively demanding. For example, the guilty suspect may experience powerful emotions (for example, fear, remorse, anger, or even excitement) that must be hidden or faked. Consider a woman publicly pleading for the safe return of her partner who, in reality, she murdered. She must monitor her body language and emotional expressions while

keeping the details of the story straight. A high level of cognitive load accompanies high-stakes deception.

Third, because liars do not take credibility for granted, they may monitor the interviewer's reactions more carefully to assess whether they appear to be getting away with their lie. Carefully monitoring the interviewer also requires cognitive resources. Fourth, liars may be preoccupied by the task of reminding themselves to act and role-play, which requires extra cognitive effort. Fifth, deception requires a justification (that is, a psychological or material reason to lie), whereas truth-telling does not. Considering a justification is mentally taxing. Sixth, liars have to suppress the truth while they are lying and this is also cognitively demanding. Finally, while the truth often comes to mind automatically, activation of the lie is more intentional and deliberate, and thus requires mental effort.

Lying is not always more cognitively demanding than truth-telling. For example, in daily life situations it is often easier to lie ("I like the present you gave me"), than to tell the truth ("I am really disappointed with this present"). The seven reasons given as to why lying is more cognitively demanding can provide insight into when it is more cognitively demanding—that is, lying is more cognitively demanding to the degree that these seven principles are in effect. For at least some of these principles to be fulfilled, two elements are required.

First, lying is likely to be more demanding than truth-telling only when interviewees are motivated to be believed. Only under those circumstances can it be assumed that liars take their credibility less for granted than truth-tellers and hence are more inclined than truth-tellers to monitor their own nonverbal and verbal behavior and/or the interviewer's reactions.

Second, for lying to be more cognitively demanding than truth-telling, liars must be able to retrieve their truthful activity easily and have a clear image of it. Only when liars' knowledge of the truth is easily and clearly accessed will it be difficult for them to suppress the truth. Similarly, truth-tellers also need to have easy access to the truth for their task of truthfully reporting an event to be relatively undemanding. If truth-tellers have to think hard to remember the event

in question (for example, because it was not distinctive or it occurred long ago), their cognitive demands may exceed the cognitive demands that liars require for fabricating a story.

### Experimental and Forensic Settings

In experimental studies, researchers ensure that interviewees are motivated (typically by giving them a reward for making a credible impression) and that the target event is easily retrieved (typically by interviewing the suspects shortly after informing them about the target event). In those experiments lying has been found to be more demanding than truth-telling in various settings. Participants who have directly assessed their own cognitive load report that lying is more cognitively demanding than truth-telling, both when elaborative and short responses were required. In functional magnetic resonance imaging (fMRI) deception research, lying and truth-telling is differentiated only by the act of pressing either a "lie" or "truth" button. Nevertheless, that research revealed that deception generally activates the higher centers of the brain associated with cognitive demand.

In forensic settings, it can reasonably be assumed that interviewees will be motivated to be believed, but it cannot be assumed that interviewees will always be able to easily retrieve from memory the target event, as this will vary from one case to another. Analyses of police interviews with real-life suspects, however, suggest that lying is often more cognitively demanding than truth-telling in the forensic setting. First, in those police interviews, lies were accompanied by increased pauses, decreased blinking, and decreased hand and finger movements, all of which are signs of cognitive load. Second, police officers who saw a selection of these police interviews (but did not know when the suspects were lying or truth-telling) reported that the suspects appeared to be thinking harder when they lied than when they told the truth. Finally, when police officers attempted to detect deceit explicitly ("Is the person lying?") or implicitly ("Is the person having to think hard?"), they were able to discriminate between liars and truth-tellers, albeit only in the implicit condition in which their attention was drawn toward the suspect's cognitive demands ("thinking hard"). In all, several findings converge on the claim that

lying is more cognitively demanding than telling the truth.

In sum, there is strong theoretical and empirical evidence that lying in interview settings is cognitively demanding, as long as liars are motivated and have a clear memory of the truth.

time more studies of deception were needed, now researchers need a way to assimilate the vast body of deception research that has accumulated over the years.

To make sense of a deception study, researchers use statistics. On results from the study, investigators conduct a primary analysis. They analyze the results of the study with descriptive statistics (like means), as well as inferential statistics (like significance tests). Sometimes, deception researchers reanalyze results that were previously published. The purpose of this secondary analysis is to clarify the earlier finding.

By contrast to primary and secondary analysis, meta-analysis offers a statistical summary of multiple studies. It is an analysis of analyses—a synthesis of many primary research findings. Meta-analysis provides techniques for cumulating the hundreds of deception studies that have already been conducted. It has been used to synthesize research on cues to deception, the accuracy of deception judgment, explanations for judgmental inaccuracies, and individual differences in judging deception.

### Meta-Analysis and Behavioral Cues

Researchers have sought cues to deception—behaviors that distinguish liars from truth-tellers. They have examined many aspects of behavior—facial behaviors (such as eye contact), bodily movements (such as torso shifts), aspects of speech content (such as self-references), and vocal variables (such as pitch). Meta-analysts have assessed the strength and direction of the relationship of deception to these various behaviors, which have been examined in more than one study.

As the accumulated evidence shows, there is no infallible cue to deceit. Cues to deception are faint. The least faint cues indicate that liars sound distant and uncertain about what they are saying. They appear nervous and ambivalent. Their remarks lack detail. To each of these generalizations, there are exceptions. Certain truth-tellers, for instance, appear more nervous than certain liars, even though people (on average) appear more nervous when lying than when telling the truth. Meta-analysis yields a precise quantitative index of the difference between liars and truth-tellers in apparent nervousness, a so-called effect size. Effect sizes have been determined for over

---

## Meta-Analysis

A meta-analysis combines and compares statistical results from more than one research study. Long ago, a researcher conducted the first study of deception. That pioneering investigator offered a few tentative observations and called for more research on the topic. A second study of deception was done, and then a third. Now deception has been studied hundreds of times. If at one

100 potential deception cues. The more strongly a behavior is diagnostic of deception, the larger is its effect size.

People make judgments of deception every day, inferring, for instance, that a coworker is lying, and that a child is telling the truth. While some investigators have sought cues to deception, others have hoped to identify the bases for deception judgment—cues from which people infer that others are being deceptive. Meta-analysis shows that behavioral variables are more strongly related to deception judgment than to deception itself. Thus, one could better predict from a murder suspect's behavior whether the suspect would be perceived as lying than whether he was, in fact, lying. People are most likely to be perceived as lying if they appear incompetent, ambivalent, or indifferent; if their remarks do not place events in context; and if they fidget. Although there is no perfect sign of apparent deception (no behavior from which every observer in the world would invariably infer deceit), cues to deception judgment are (statistically speaking) stronger than deception cues. Precise effect-sizes for many judgment cues are available.

### Meta-Analysis and Lie Detection Ability

How successful are people when they make judgments of deception in everyday life? They are not very successful, meta-analytic evidence suggests. In hundreds of studies people have judged a series of messages (half-lies and half-truths), and upon encountering each message indicated whether it was a lie or the truth. By flipping a coin, the judges in these studies would have successfully guessed the truthfulness of 50 percent of the messages they encountered. In fact, they successfully judged the truthfulness of 54 percent of messages. This is the average finding in some 200 studies. Results are consistent across studies, with one exception. In a few very small studies, judges appear to be highly accurate; in a few other very small studies, they appear to be highly inaccurate. Meta-analysts regard these discrepant results as chance outliers.

Why are people so poor at detecting lies? One possibility is that there are no strong cues to deception. Another is that in trying to detect deceit, people ignore valid cues and base their deception judgments on other, misleading cues. A

meta-analysis was conducted to assess these possibilities. The pattern of evidence indicates that deficiencies in lie detection reflect an absence of good deception cues. Given the weak cues at their disposal, people detect almost as many lies as possible. They base their judgments of deception on the best cues available—imperfect though those cues may be.

Although most people are barely able to detect lies, there may be individual differences in lie detection ability. Perhaps some people are lie detection “wizards” (extraordinarily gifted at lie detection) while others are lie detection “dunces” (regularly confusing lies and truths). A meta-analysis of hundreds of studies belies this individual difference hypothesis. Yes, in every study research participants differ in the number of lies (and truths) they judge correctly. However, these differences are no greater than would be expected by chance. As probability theory would predict, individual differences in percentage correct are large when research participants judge only a few messages; they are small when participants judge many messages.

Long lie detection tests reduce the impact of guessing on apparent differences. Unfortunately, most lie detection tests are brief. Thus, there are apparent differences in lie detection performance but hardly any real differences from person to person in the ability to detect lies. This may explain why at a meta-analytic level differences in lie detection performances show no consistent relationship to the detector's sex, age, confidence, or experience.

While discriminating lies from truths at levels slightly better than chance, people are inclined to see others as more truthful than deceptive. In a typical study, in which people encounter half-lies and half-truths, they perceive roughly 56 percent of those messages as truths. There are individual differences in this tendency. Some people are more suspicious than others. They regard every message they encounter as a lie. The highly suspicious might seem to have a special gift at spotting deceit. They are also, however, highly inaccurate at judging truths. Blanket suspicion is not judgmental acumen.

There are also individual differences in detectability. As noted, observers achieve 54 percent accuracy in discriminating an average person's lies

from that same person's truths. However, some people tell lies and truths that can be discriminated at higher levels (say, 59 percent). Other people tell lies and truths that are completely indiscriminable (being correctly judged, for example, 50 percent of the time). Thus, meta-analysis confirms the colloquial saying—some people are easier to read than others.

The largest individual difference in this area is not, however, a difference in chronic suspicion or ease of detectability. It is a difference in apparent honesty. Some people appear more truthful than others. As noted above, the average person's lies and truths are seen as truths 56 percent of the time. However, some people are seen as truthful much more often (say, 68 percent of the time), while others are seen as truthful much less often (say, 44 percent of the time). People who appear honest when telling the truth also appear honest when lying. It is said that they have an honest demeanor and that deception judgments are subject to a demeanor bias.

### Meta-Analysts' View of Deception Research

Research on deception has been criticized. Most of the research has been conducted on college students who have been prompted to lie and who have no incentive to get away with the deceit. Even so, there are studies of deception by criminals, work on naturally occurring lies, and research on motivated liars. Some investigators dismiss studies of students' deceptions out of hand, as though those studies have no evidentiary value. Likewise, they dismiss studies of experimentally prompted lies and research on unmotivated lies. Such studies need not be considered, these investigators believe.

Meta-analysts take a different view. They include in their statistical reviews all evidence that might conceivably be relevant to an understanding of deception. Then they examine results within various subsets of the research literature to see whether factors that are hypothesized to affect research results do, in fact, affect those results.

Statisticians have developed meta-analytic techniques for assessing the impact of cross-study factors on research outcomes. Technically speaking, the relevant analyses determine whether the typical findings of deception research are moderated by differences among research participants (students versus nonstudents), differences in the

prompting of lies (prompted versus spontaneous), and differences in incentives (motivation versus no motivation to lie).

In the main, the findings of deception research generalize across different types of studies. On the average, people are barely able to detect lies from truths even if the liars are nonstudents, even if the lies are spontaneous, and even if the lies are highly motivated. In studies of nonstudents, studies of spontaneous lies, and studies of motivated lies, people vary widely in apparent honesty, and they barely differ from one another in the ability to detect lies. While a few cues to deception may be less faint in some types of studies than others, no cue ever studied has ever approached infallibility. Thus, people may speak at a nontrivially higher pitch when telling a motivated lie than when telling the truth. However, no credible lie detection technology could be built on a difference of this magnitude.

The behavioral signs of deception are weak. As a consequence, people have difficulty determining when others are lying. There are no strong individual differences in the ability to judge others' deceptions, but some people appear more truthful than others. Lie detection is not strongly affected by factors that one might expect to affect it (like motivation for the lie). Precise quantitative conclusions on these issues are afforded by meta-analysis—a set of statistical techniques for combining and comparing research results.

## Microfacial Expressions

Microfacial expressions, more commonly called microexpressions, are involuntary and fleeting facial expressions that reveal an individual’s experience of an emotion. Microexpressions can last anywhere from 1/5 to 1/25 of a second. The seven basic facial expressions—happiness, sadness, anger, contempt, surprise, fear, and disgust—can all be expressed as microexpressions. Research indicates that the stronger the emotion the more difficult it is to conceal, with fear being the most difficult to conceal and happiness the easiest.

Microexpressions were first described in the 1960s by researchers examining nonverbal communication during psychotherapy sessions. The researchers slowed the videotapes of patient and therapist interactions to discover “micromomentary” expressions produced by patients that lasted less than one-fifth of a second. Paul Ekman and his colleagues later connected microexpressions to the concept of deception detection by theorizing that microexpressions were involuntarily leaked emotions associated with the deception, such as guilt, shame, or anger, that a person was trying to mask, or the feigning of an emotion, such as smiling when upset. Ekman noted that the face has many muscles that are not typically under voluntary control, making microexpressions difficult to feign, while nonverbal behaviors in the rest of the body can be masked through conscious effort.

The use of microexpressions as a method for detecting deception quickly became popular among professionals in the deception detection field. Police manuals and training programs frequently discussed microexpressions as an important tool for detecting deception, often with claims that microexpression analysis could lead to high-accuracy deception detection. Microexpression’s usefulness for detecting deception was also popularized for the general public, with television

*An airport agent checks a passenger’s identification before allowing her to proceed through security, March 29, 2013. A large-scale, controversial program called Screening Passengers by Observational Techniques is based on detecting microexpressions.*

shows such as *Lie to Me* showing the main character catching liars through his ability to identify microexpressions.

Despite professional and popular conceptions of microexpressions, however, there have been few peer-reviewed scientific articles that have examined the relationship between microexpressions and deception. The first peer-reviewed study to examine the relationship between microexpressions and deception was not published until 2008, and found only partial support for Ekman’s idea that microexpressions can reveal a masked emotion. Consistent with that idea, microexpressions occurred more often when participants were trying to mask an emotion, especially under higher stakes, than during genuine expressions. Microexpressions, however, were also observed during genuine emotional displays, indicating that they are not solely related to masked emotions. Additionally, microexpressions were rarely full-face emotional expressions; rather, what often were leaked were partial expressions occurring only in smaller, specific areas of the face. Overall, microexpressions were extremely rare, suggesting that they may not be very useful in detecting deception in general. Further, microexpressions may not be as “micro” as previously believed, with some of the inconsistent expressions lasting more than one second.

### Tools to Measure Microexpressions

There is evidence suggesting that people can learn to identify microexpressions, especially with the help of training programs. Several tools have been created to measure when and which microexpressions are expressed. Since 1978, the facial action coding system (FACS) has manually and systematically coded facial expressions. FACS is used to trace every muscle movement in the face in order to help researchers learn to detect and categorize those movements. FACS can be used to determine whether a person is attempting to mask emotions by breaking each emotion into components.

The micro expression training tool (METT) has also been used to improve accuracy in detecting microexpressions through a pretest and posttest of facial analyses. This training involves learning about the various facial components of the seven major emotions, and the user is asked to determine a flashed microexpression. Similarly, the subtle expression training tool (SETT) was developed after new research was released about partial expressions. Users of SETT are asked to determine if the hidden emotion of the person on the screen is based on a microexpression on only part of the face. Proponents of METT and SETT argue that after training, reading microexpressions can increase social and communicative skills. Both methods are used for training professionals in fields in which deception detection is vital.

A large-scale program based on microexpressions is the controversial airport screening program Screening Passengers by Observational Techniques (SPOT). This program trains airport security officers to search for clues in passenger behavior, such as microexpressions, that may reveal individuals intent on terrorism. One report claimed that SPOT allowed officers to catch liars with high levels of accuracy. According to a congressional report, however, while SPOT singled out 50,000 people in 2010, only 300 were arrested, suggesting a very high false-positive rate. All arrests were for drug possession, falsified documentation, or other offenses unrelated to terrorism. Earlier reports had at least 17 known terrorists passing through 23 SPOT program airports undetected. The recent research suggesting that microexpressions are rare and can also take place during genuine emotional displays has also raised concerns about the program.

While microexpressions are brief facial flashes of emotion that may reveal hints about a true emotional state, they are not a conclusive method of deception detection.

## Middle East

Efforts to understand human behaviors such as lying and deception must address a multiplicity of ecological contexts that influence individual development, which in turn influence the environments

in which individual development—including cognitive, social, and moral development—takes place. The ecological model, developed by Urie Bronfenbrenner and later refined by Jay Belsky, takes into account variables influencing behavior at four levels of analysis: the individual, the microsystem, the exosystem, and the macrosystem.

The individual/developmental level includes biological/genetic factors, gender, age, personality, cognition, and emotional characteristics. These variables are embedded within the microsystem, which includes the individual's proximal social environment such as family members. In turn, microsystem factors are located within the exosystem, which includes experiences within the community and with local groups. Finally, beyond these more immediate contexts, individuals are influenced by their macrosystems, which include broad national and cultural forces. To understand the causes and roles of lying and deception in the Middle East, it is necessary to understand how globalization and modernization have influenced the psychological functioning of individuals living in that region today.

### **Effect of Modernization**

Historically, truth-telling and honesty were necessary and respected values and traits in Middle Eastern cultures. Arabs have been nomadic and tribal since the dawn of history, living in harsh desert environments with limited resources. They had to rely on each other and social relations for survival. Within this context, honesty and truth-telling became essential because lies and deception could mislead and harm the group regarding the reality of their relationships, natural environment, and the capabilities of themselves and their enemies.

All three of the major Middle Eastern religions, Judaism, Christianity, and Islam, prohibited lying and deception and encouraged truth-telling and devotion to keeping promises. Moreover, lying and deception were mostly ineffective as paths to advancement because social status was determined by tribal lineage and performance in trade or war. In a small tribal society, in which people know almost everything about each other since childhood, there is little room for lying and deception, and if it occurs, it can be detected and dealt with quickly.

With modernization, governmental centralization, and urbanization of the Middle East, there have been increases in individualism and mobilization, changes in political management and control, and the mixing of people from various backgrounds in urban areas. These kinds of macrosystem changes can produce social fragmentation, anomie, increases in self-interest, and the quest for personal wealth and power, all of which can increase levels of moral disengagement. As described by Albert Bandura and others, moral disengagement is an individual-level set of cognitive processes that allow individuals to morally disconnect from their own immoral behavior, so that they can behave inhumanely while continuing to view themselves as ethical people. Corrupt leaders can foster such moral disengagement in ordinary people in ways that lead these people to accept or participate in various forms of extremism.

Within many exosystems in the Middle East, such changes gave more freedom to some individuals to use lying and deception for personal or political gains without feelings of guilt and without the old fears of being caught easily or of loss of social status. A web of lies and deception creates an illusion of justice and development and a shared myth that “everything is okay.” In such circumstances, lying and deception are acceptable as long as they enforce the status quo and the dominant narrative, and truth-telling and honest opinion can be considered heroic or dangerous, if not illegal and naive. In addition, oppressive systems dictate what the “truth” is, enforce certain narratives, and silence any voice or opinion that might challenge that narrative. On the other hand, under oppressive and corrupt systems that deny some basic human rights and needs, and which are built on a fabric of deceptions and lies, lying and deception can become a way for individuals to assert their freedoms and get their legitimate survival needs met.

### **Corruption, War, and Radicalization**

Corruption in various sectors of government and businesses is a major problem in the Middle East today. Such corruption utilizes lying and deception as tools to exist. It contributes to economic and social underdevelopment and waste of resources. It also facilitates the accumulation of wealth and power in the hands of the few. Ironically, it creates

an environment in which lying and deception become necessary in order to “get things done,” and at the same time erodes national and international trust in economic processes. Such corruption resists the transparency and accountability required to attract international investments and for economic development.

The Middle East has been a constant theater for invasions and wars. Lies and deception are important components in creating acceptable contexts for war, in moral disengagement, in propaganda before and during wars, and in efforts to cover up the atrocities of war. Thus, individuals in the Middle East are faced with the challenge of identifying what is real and what is not from a large amount of lies and deception that affect their lives in various ways, on local, national, and international levels.

The constant presence of such lies in the lives of people in the Middle East, and sometimes in stereotypes about its realities and people, contributes to mistrust and cynicism among some. It also contributes to a sense of helplessness and repeated disappointments, especially among the youth, when idealism conflicts with the mysterious reality that seems to function according to unknown rules. Such encounters bring the youth to crossroads, where it might seem to them that they have to either abandon their idealism and higher values in order to function in society, or to keep adhering to their values and risk being marginalized, disrespected, and having most of their needs unmet. This situation is one of the factors contributing to radicalization in the Middle East. Radicalization can be seen as an effort to adhere to the “pure truth” in the face of lies, deception, and corruption.

## Military Deception

Military tactics often seek to obtain advantage through deception, actively pursuing this type of strategy in order to enhance the odds of a victorious outcome. Misleading the enemy in a secretive manner is accomplished through multiple approaches, each of which involves introducing uncertainty and maintaining the element of surprise. Stratagem encompasses the various forms of tactics utilized by the military to deceive enemies and serves to produce benefits without reducing a significant amount of resources in the process. Although the circumstances necessary for military troops to gain an advantage over the enemy may vary, deception plays an integral part in the success of any military campaign.

The significance of deceptive warfare strategies is well documented in historical military operations and is often cited in texts concerning military warfare strategies. Seminal works on warfare strategy, such as *The Art of War* by Sun Tzu, emphasize its importance in the planning stages

of any battle. The examination of numerous historical military operations reveals that several of the most notable victories throughout history benefited from this type of tactic.

Interestingly, military theory does not reference deception as a stable tactic to be utilized by all. This could be because prior to the 20th century deceptive tactics were normally created and implemented by small groups of individuals. Today's military environment instead relies on a centralized chain of military command, in which all tactics and strategies are promulgated via a top-down approach. Regardless, deception has always been, and remains, an important component of the vast majority of successful warfare strategies.

### **Deceptive Strategies**

Incorporating deception in a military campaign is generally accomplished via two interrelated approaches. Strategies are formulated to mislead opponents concerning information critical to maintaining a tactical advantage; the nature of a military unit's activities, the potential plan of attack, as well as the true motives for acting in a specific manner, are misrepresented to the enemy. Camouflaging this type of critical information enables military personnel to maintain security while still advancing their position.

Additionally, deceptive strategies serve to keep details regarding strengths and weaknesses hidden from a potential enemy, thus reducing the ability to properly prepare for an impending encounter. This type of tactic, when employed effectively, serves the purpose of providing military personnel with a strategic advantage over the enemy. Intellectual resources, such as knowledge regarding the enemy's abilities, or information the enemy would benefit from, are useful in the calculation of a sound deceptive strategy.

Deceptive military strategies, commonly referred to as stratagem, share a specific group of factors necessary for any ruse to be successful. One of the key tasks of stratagem is to maintain the element of surprise. A military unit gains a significant advantage anytime its strategy departs from what the enemy perceives as the expected plan of attack. In fact, the element of surprise has been emphasized as an important warfare principle by several military stratagem theorists,

including Barton Whaley. More specifically, military commanders plotting deceptive strategies that aim to sustain surprise purposefully introduce uncertainty into the minds of the enemy. By incorporating uncertainty into an enemy's perception concerning an impending attack, battlefield commanders are able to reduce the level of overall risk to their own personnel and resources, while at the same time exponentially increasing the odds of success.

Military deception is often enacted through the use of diversion, which may stem from several different methodologies, which all have the singular purpose of creating uncertainty in the mind of the enemy. One method, known as the *feint*, provides the enemy with a misrepresentation regarding the nature of a suspected attack. A *feint* gives the false impression that an upcoming attack will be implemented in a particular way in order to distract the enemy from the true intended target or goal.

Another form of diversion consists of deceiving one's enemy about the onset of the main attack through the use of a small force. This tactic attempts to draw the enemy into battle prematurely by convincing the enemy that it is engaging the main force, only to discover that another more forceful attack is yet to come. This type of ruse causes the enemy to expend valuable personnel and other resources, while also serving to expose their exact position and strength.

### **Disinformation**

One of the most subtle forms of military deception involves the inventive use of communication. Deceptive communication involves purposely providing information that is inaccurate to the enemy. Military stratagem of this method highlights the importance of knowing the enemy's communication preferences; it is essential to make the disinformation available to the enemy in a manner that conceals its origin. In order for this to occur successfully the inaccurate information must be delivered inconspicuously through a channel of communication that the enemy frequently utilizes. Implanting the disinformation in a location, or via a resource, that is trusted by the enemy is a key component of this tactic.

Disinformation is communicated through various avenues, such as word of mouth, newspapers,

and military radio. Disseminating a fraudulent claim, or plan, verbally to various sources with which the enemy interacts increases the likelihood that the information will reach the enemy in a timely manner, and from a trusted source. This form of communication provides an aspect of authenticity to the disinformation, thus increasing the odds the enemy will accept it as reliable. Other channels of communication involve the use of official sources, which may further mask the deceptive nature of the information provided. Military officials may utilize the newspaper or other popular media to purposely leak disinformation, which attracts the attention of journalists, who subsequently print the disinformation as if it were factual.

The use of military radio transmission in order to spread disinformation has historically proved an effective form of delivery, but it relies on the enemy's ability to gain access to otherwise secure lines of communication. In this case, the

disinformation is stated clearly, or in a manner that is simple for enemies to decipher, in order to ensure that they receive the information exactly as intended. An additional layer of deception is added when military officials deliver disinformation that appears to be accidental, so that enemy officials believe they have stumbled upon factual information that was meant to be kept secret.

### Operation Mincemeat

Operation Mincemeat, an elaborate ruse in which the British took advantage of Germany's connection to Spanish secret intelligence in order to divert their attention away from the predicted location of the English invasion during World War II, is a classic example of this type of military operation. Although planting disinformation in the enemy's line of sight was a common technique for British military personnel, Operation Mincemeat was particularly noteworthy because of its innovative use of resources to deceive Germany

*Performing an early morning operation to catch insurgents by surprise, British soldiers kneel on the ground while moving into position in the town of Pasab, Afghanistan, March 5, 2011. One of the key tasks of stratagem is to maintain the element of surprise. A military unit gains a significant advantage when its strategy departs from what the enemy perceives as the expected plan of attack.*

during a time in which the location for a future plan of attack was suspected. In early 1943, while growing increasingly suspicious of England, German military officials predicted that the likely target for a British invasion would be Sicily. Operation Mincemeat was coordinated by a committee of British military intelligence (MI5) specifically to deceive Germany's military intelligence into believing that the plan was to invade through Sardinia or Greece rather than Sicily.

In order to ensure that German intelligence would receive the required information while remaining unaware of its inaccuracy, the body of a man dressed as British officer was released into the waters off the coast near Spain on April 30, 1943. The body was planted with official-looking documents containing fraudulent plots for an impending British invasion. As planned, the decoy was retrieved by Spanish intelligence a week later and promptly turned over to German military hierarchy. As a result, the German commanders immediately altered their defense efforts with a new focus on Sardinia. Exploiting existing lines of communication between Spain and Germany as well as the trust established between the two nations played an invaluable role in ensuring that the Germans accepted the information as being both credible and reliable.

A critical element of the ruse was the use of a resource that by all appearances was incredibly reliable and seemingly trustworthy; a body resembling a deceased British military courier who could be reasonably expected to have this type of sensitive information gave credibility to the information recovered from the body. Operation Mincemeat is a prime example of the critical role that deception can play in successful military operations.

Well-planned and implemented deceptive strategies place an enemy in a predicament in which at the very least it is forced to expend precious time and resources both validating and reacting to the planted disinformation, often resulting in the enemy commanders making costly errors in the planning and execution of their operations. Military deception strategists purposefully create a situation in which the enemy is likely to choose the exact alternative plan of action that the deceiving military planners desire. The direct result of this type of operation is that the deceptive force gains

the invaluable element of surprise on the battlefield, while the enemy is manipulated into taking actions in direct opposition to their best interests.

## Miller, Gerald

Gerald R. Miller (1931–93), known as Gerry or G. R., has often been referred to as the father of interpersonal communication research. Described by many of his colleagues as someone who was larger than life, he possessed a booming laugh, lightning-quick humor, and a penchant for witty limericks and chocolate. He eschewed the computer, preferring the typewriter to craft his contributions to the field of communication.

Miller completed his Ph.D. in 1961 at the University of Iowa. After one year at the University of Washington, he arrived, and stayed, at Michigan State University in what would become the Department of Communication. He was a departmental chair and a recipient of both the Distinguished

Faculty and University Distinguished Professor awards at Michigan State. The Gerald R. Miller Outstanding Doctoral Dissertation Award presented by the National Communication Association is named after him. He also was the founding editor of *Human Communication Research*.

In an article commemorating Miller, one of his former students and colleagues, Frank Boster, stated that the interpersonal communication book *Between People* (1975), coauthored by Miller and Mark Steinberg, generated the lines of deception research pursued by Miller and his students. These lines provided both creative methodological designs as well as significant contributions to the deception literature.

### Miller's Research

In 1979, Miller and colleagues published their study examining deception detection accuracy and verbal, vocal, and visual cues, in which participants judged videotapes of a speaker's head and body, a close up of the face or only the body. The study also varied because the videotape was filmed in both black and white and in color and included audio and visual cues or only visual cues. In 1980, Miller and colleagues published a study examining how familiarity with another person's communication behaviors and style affected deception detection accuracy. This type of work is known as a baseline study because it gave observers a baseline of communication behaviors to compare to the communication behaviors that were being judged for deception.

In 1985, Miller and Mark deTurck published a study that introduced an "aroused truthful" condition, in which arousal was induced in some research participants by subjecting them to intermittent bursts of white noise, prior to and during an interview. Thus, they were able to delineate cues that were elicited by general arousal from those elicited by deception. In 1986, Miller and James Stiff published their study examining how probing influences deception detection accuracy. Speakers were either positively probed by experimenters who agreed with the speakers' comments or negatively probed by experimenters who were skeptical of the speakers' comments. These conversations were videotaped and judged by participants for deception. In 1993, Miller & Stiff's book *Deceptive Communication* was published.

The last graduate seminar Miller taught at Michigan State University before succumbing to cancer was a doctoral seminar on deception. The legacy of G. R. Miller and his continuing contributions to the field of interpersonal communication and the literature on deception live on in the work of students who knew him as their professor, mentor, colleague, and friend.

## Mimicry

Mimicry is one of nature's master devices of deception. In nature, mimicry can serve a protective purpose by signaling a warning, disappearing into the background, or warding off predators.

Predators have mastered mimicry for aggressive means as well, mostly to lure unsuspecting prey or to even masquerade as nonthreatening. Humans have also relied on mimicry for deception, most notably in military warfare, using mimicry to feign retreats and intimidate enemies. Humans engage in deceptive mimicry outside of warfare, such as in interpersonal contexts, but research on human mimicry has only begun, with most progress stemming from economic theory.

### Animal Mimicry

Under the damp, shady canopy of the Amazonian rainforest, Henry Walter Bates—the naturalist for whom the first type of mimicry (Batesian mimicry) is named—first discovered mimicry when he observed two different species of butterflies that looked profoundly similar. Studying the *Heliconius* butterfly and its mimic, the *Leptalis*, Bates reasoned that the prey (*Leptalis*) used mimicry to deceive the predator.

In Batesian mimicry, the purpose of the deception is protection. In the constant struggle between prey and predator, mimicry is a strategic ploy. Batesian mimicry assumes that only one species needs to be unpalatable to the predator. For instance, the *Heliconius* releases a pungent odor and skin irritant from its body when attacked, making it an undesirable target. The palatable mimic imitates the first species. The *Leptalis*'s wings are almost identical copies of the *Heliconius*'s, deceiving predators into perceiving it as unpalatable. By using mimicry, the succulent *Leptalis* is protected, or rather, untargeted by predators.

Another example of Batesian mimicry is the Sonoran mountain king snake's mimicry of the toxic coral snake. The Sonoran mountain snake effectively mimics the black-red-and-yellow stripe pattern of the coral snake, which serves as a warning sign of the coral snake's highly poisonous venom. The mimicry is almost flawless, and only the order of the colors can indicate whether the snake is toxic or harmless.

German naturalist Fritz Muller observed that harmless, attractive prey are not the only ones to use mimicry for protection. In Mullerian mimicry, multiple noxious-when-eaten species mimic each other, ultimately resembling others for protection against predators. If two, three, or

even four similarly noxious species mimic each other, their chances of survival will exponentially increase, because when a predator attacks one species the predator learns to avoid all of the mimicking species. The predator is duped into perceiving that each species mimicking the other is noxious. The previously mentioned unpalatable *Heliconius* butterfly engages in this type of mimicry. *H. numata*, *H. erato*, and *H. melpomene* (various species of the *Heliconius* butterfly) are part of the same Mullerian mimicry group in that they all mimic each other, and predators that feed on butterflies learn to avoid the entire group as a whole.

Animals do not always mimic other animals; they can also mimic the environment. The *Kalima* butterfly's wings are a nearly perfect imitation of a leaf, allowing it to blend into a forest background to camouflage it from predators. The Indo-Malaysian octopus is a master of deception with its ability to mimic both other animals, such as flounders and sea snakes, and the environment, taking on the appearance of surrounding rocks or the sea floor.

Nature employs mimicry not only for defensive but also for aggressive purposes. In aggressive mimicry, the predator is "a wolf in sheep's clothing." Mimicry is used to appear harmless or even attractive to lure its prey. A bird-dropping spider uses mimicry by imitating the appearance of bird-droppings, a delectable meal for flies. Attracted to the bait, flies are deceived by the mimicry approach, only to be captured by the spider. In another example, the Malaysian orchid mantis mimics the structure of an orchid to catch deceived flies attracted by the nectar of the seemingly harmless orchid.

In mimicry, appearance is not the only characteristic that is deceiving. Mimicry can be in the form of scent, sound, and even touch. The rebel large blue butterfly's caterpillar mimics the chemical scents of an ant, deceiving ants into carrying it into their nests, protecting, feeding, and raising it. The deception is twofold: the caterpillar not only mimics the scent but also the sound of an ant queen, giving it even more preferential treatment from the fooled ants. The *stenolemus bituberus* insect mimics an insect caught in a spider's web, cutting the web and sending vibrations to the spider signaling that a prey has been caught.

When the spider approaches to feed on its victim, *stenolemus bituberus* preys on the deceived spider.

### Human Mimicry

Animals are not the only species to use mimicry for survival. Humans employ mimicry in military warfare. Deceptive mimicry has been successfully used for protection, often attempting to fool the enemy by mimicking a larger army. A famous historical example of this occurred during the U.S. Civil War. Confederate General John Magruder's force of 8,000 men held off a Union Army force of more than 120,000 by creating scarecrows that mimicked soldiers. This gave the illusion that the army was 10 times bigger than it actually was. The Trojan Horse is another famous example, in which the Greek army deceptively mimicked a retreating army and accordingly supplied a large wooden horse to the Trojans as a gift of their victory. The retreat was a hoax and the wooden horse was a trap. The Greeks' mimicry of a retreating army successfully deceived the Trojans and gained the Greeks access to Troy.

Economic theory explains the possible incentives that lead to deceptive mimicry. In an economic scenario, an individual usually gains some type of advantage (economic, social, physical) by utilizing mimicry. When the rewards largely outweigh the costs, deceptive mimicry is desirable. For instance, the costs of impersonating a wealthy chief executive officer (copying mannerisms and dress) are negligible compared to the possible gains, such as preferential treatment, social status, and economic advantages. Consider the famous example of Frank William Abagnale Jr. from the film *Catch Me If You Can*, who successfully deceived others into believing he was a pilot, a doctor, an attorney, and a member of many other occupations. For Abagnale, the benefits of deceptive mimicry, such as wealth, social status, and respect, outweighed the costs of forging checks and diplomas, copying dress and mannerisms, or experiencing any feelings of guilt. Another example in a consumer culture can be seen from the coffee chain Starbucks, as it chooses to give free coffee to the first 10 doctors who enter a Starbucks's store on a particular day. A mimicker who dresses as a doctor obtains the free cup of coffee, while a real doctor whose place was taken loses.

### Conclusion

Nature and humans both use mimicry as a form of deception. In nature, deception through mimicry is a key form of protection for animals like the *Heliconius* and *Leptalis* butterflies. Likewise, mimicry can also be vital for attacking, such as for the caterpillar of the rebel large blue butterfly. Humans also rely on the potential advantages of mimicry, including strategies of mimicry in military warfare and, when the gains outweigh the costs, in interpersonal contexts.

## Morals and Ethics

The utilitarian moral philosopher Jeremy Bentham (1748–1832) once said that there is nothing intrinsically, morally wrong with lying: "Falsehood, take it by itself, consider it as not being accompanied by any other material circumstances, nor therefore productive of any material effects, can never, upon the principle of utility, constitute any offense at all."

For strict consequentialists such as Bentham, the moral wrongness of lying and deceiving lies in the consequences of lying and deceiving. Even if all lies and deception were morally wrong, they would be so because of their bad consequences,

and nothing else. If this were true, then there would be nothing special about acts of lying and deceiving. In themselves, they would be morally neutral acts. Furthermore, if lying and deceiving happened to have no bad consequences, then they would not be morally wrong. If telling lies and deceiving people happened to have good consequences overall, then it would be morally obligatory to lie and deceive.

### Nonconsequentialist View of Lying

Nonconsequentialist moral philosophers have argued that lying and deception are morally wrong, and not merely because of their bad consequences. Lying and deception have what Sissela Bok has called an “initial negative weight,” and are not morally neutral acts. According to these philosophers, lying and deceiving are morally wrong even if they have no bad consequences. Lying and deception are morally wrong even if they have good consequences.

The question is whether any of these philosophers can successfully defend the position that lying and deception are morally wrong without appealing to some form of harm to others, which is an appeal to bad consequences. Also, there remains the question of whether, if lies and deception are morally wrong for reasons other than their consequences, they are nevertheless sometimes morally permissible, or are always morally wrong. Finally, there remains the question of whether lying is always worse than deceiving without lying, or whether deceiving without lying can be just as morally wrong, or worse, than lying.

One argument for the moral wrongfulness of lying can be found in the work of W. D. Ross, Roderick M. Chisholm, and Thomas D. Feehan and Charles Fried. According to Ross, every time a person makes an assertion, she or he makes an implicit promise not to lie: “the implicit undertaking not to tell lies which seems to be implied in the act of entering into a conversation (at any rate by civilized men).” According to Chisholm and Feehan, in telling a lie, the liar “gives an indication that he is expressing his own opinion.” And he does this in a special way—by getting his victim to place his faith in him.” Fried also holds that “An assertion may be seen as a very general promise: it is a promise or assurance that

the statement is true.” As a result, “Every lie is a broken promise, and the only reason this seems strained is that in lying the promise is made and broken at the same moment.” Every lie, therefore, is “a breach of trust,” and it is morally wrong for an individual to invite someone to trust them and to violate that trust.

One problem with this argument is that it may not be true that assertions necessarily involve a promise that the person is being truthful. However, even if every assertion were said to involve such a promise, this argument would seem to make lies a species of broken promises. That is problematic, since, as Marcus Singer has said, the claim that “it is always wrong to break a promise . . . is even less plausible than the proposition” that lying is always morally wrong. Lying would appear to be more morally egregious and a greater violation of trust than breaking a promise.

### Undermining Trust in Society

Numerous writers on lying and deceiving have argued that they are morally wrong because they undermine trust in society, which leads to the breakdown of society. This argument is a consequentialist argument because the moral wrongfulness of lying and deceiving stems from the bad consequences of undermining trust and not from the violation of trust itself. If it happened to be true that society could survive with little or no trust, then this argument would not morally prohibit lying. It remains a matter of controversy to what extent lying and deceiving undermines trust in society.

Studies by psychologists and sociologists appear to reveal that people lie and deceive on a daily basis. If this is true, then either a great amount of lying and deceiving fails to undermine trust in society (because the lying is sufficiently compartmentalized, and/or is tolerated), or society can survive with much less trust than previously thought. Furthermore, there are contexts, such as wars, in which, according to William Glenney, “there is no explicit expectation of trust.” This may also be true in business negotiations, according to Thomas L. Carson. There is evidence that investors know that there is widespread lying and deception about, for example, the value of stocks, and that this does not impede investment. As Brooke Harrington has said, “widely held

beliefs about the need for public trust in financial markets may be unfounded.” People are still capable of lying and deceiving in such contexts, in which there is little or no trust to undermine. It is not clear if this argument would be unable to find lying and deceiving in such contexts morally wrong at all.

### Augustine, Aquinas, and Kant on Lying

Nonconsequentialist moral philosophers have given more elaborate arguments as to why lying and deceiving are morally wrong. Saint Augustine (354–430) argued speech is a gift from God, given to use, as His gift, for the purpose of expressing what is thought. When people lie they appropriate speech, something that does not belong to them, to express what they do not think, a purpose contradictory to its intended purpose. This prideful appropriation of speech as something of their own, when it is actually God’s gift, ruptures their relationship with God and disrupts a graced world of ordered being, goodness, and love. This is why lying is morally wrong.

This is a purely religious argument for the moral wrongness of lying. It relies upon accepting that speech is a gift from a beneficent God that nevertheless remains God’s and may not be used except in the way that it was intended to be used. Should God’s existence be denied, or should it be argued that gifts may be used in any way that the recipient pleases, the argument would fail to morally prohibit lying.

Saint Thomas Aquinas (1225–74) argued that all lies are “inherently evil” because “Words by their nature being signs of thought, it is contrary to their nature and out of order for anyone to convey in words something other than what he thinks.” Language naturally signifies thought, hence it is contrary to the nature of language to signify what is not thought, which is to lie. Such an argument, importantly, makes no reference to the effect of this “disordered” use of language on others. This argument against lying relies upon a claim about the nature of language that requires support: is the sole natural function of language to communicate what is being thought by the speaker?

More important, however, even if communication of what is being thought is the only or most important natural function of language, it is not

clear why it is ever morally wrong to act contrary to nature. If masturbation or homosexual acts were said to be contrary to nature, because it was held that the natural function of sex is to reproduce, this would surely not be sufficient to make either of them morally wrong. If it is argued that the natural order has been created by God, and that acting contrary to nature is acting contrary to God’s natural order, then Aquinas’s argument against lying would become a purely religious argument for the moral wrongness of lying.

Immanuel Kant (1724–1804) had several arguments against lying. In *The Metaphysics of Morals* (1797–98) he argued that the moral wrongness of lying consists in what one does to oneself when one lies (either to oneself or to others). The human being, as a natural being, has a natural capacity to communicate her thoughts. The human being, as a moral being, can use the human being, as a natural being, to communicate her thoughts (either to herself or to others). However, the human being, as a moral being, can also use the human being, as a natural being, to communicate what are not her thoughts. To do this is to lie.

When one lies, one (as a moral being) uses oneself (as a natural being) as a mere means to an end. When one lies, one (as a moral being) treats oneself (as a natural being) as a “speaking machine,” that is, as a thing:

The human being as a moral being (*homo noumenon*) cannot use himself as a natural being (*homo phaenomenon*) as a mere means (a speaking machine), as if his natural being were not bound to the inner end (of communicating thoughts), but is bound to the condition of using himself as a natural being in agreement with the declaration (*declaratio*) of his moral being and is under an obligation to himself to truthfulness.

Since to lie is to use oneself, as a natural being, as a mere means to an end, it follows that to lie is to treat oneself as something less than a human being: “By a lie a human being throws away and, as it were, annihilates his dignity as a human being.” There are several problems with this argument. First, it is unclear what it means to divide a person into a moral being and a natural being. Second, it is unclear if there are any moral

Sandro Botticelli's fresco of Saint Augustine (1480). Augustine argued that lying is morally wrong because it is a prideful appropriation of speech, which is given as God's gift. He stated that lying ruptures a person's relationship with God and disrupts a graced world of ordered being, goodness, and love.

duties to oneself. Most importantly, however, it is unclear why it is morally wrong to use oneself as a natural being—to use oneself as a body—as a mere means to an end one has as a moral being. It is unclear why treating one's own body as a thing, for one's own ends, is morally wrong. Kant attempts to show that it is morally wrong to have sex purely for pleasure using a similar argument, and this is surely mistaken.

### Effect of Lying on Others

These arguments for the moral wrongfulness of lying from Augustine, Aquinas, and Kant make no mention of other people, although it is surely

plausible that the moral wrongfulness of lying and deceiving has something to do with how one treats or affects other people by lying to them or deceiving them. In the *Groundwork of the Metaphysics of Morals* (1785), Kant has a more famous argument against lying that does make reference to other people. Kant argues that when one lies or deceives, one treats other people as inferiors rather than as equals.

His argument is as follows: When one tells a lie, one acts on a rule of the following kind: in order to achieve some end, I will lie. For example, in order to get money, I will lie that I am only borrowing money. Lying to get money will only succeed so long as it is not the case that everyone else is lying to get money. If everyone attempted to get money by lying, then nobody would ever get any money, because nobody would be believed when they asked to borrow money. A liar, of necessity, applies a double standard: lying is permissible for me, but not for anyone else. A liar has one rule for herself (in order to achieve some end, lie) and another rule for everyone else (don't lie). As Kant says, "we do not really will that our maxim should become a universal law . . . but that the opposite of our maxim should instead remain a universal law, only we take the liberty of making an exception to it for ourselves."

The basis for applying a double standard, or having one rule for oneself and another for everyone else, is a presumption of inequality. It is permissible for one to lie, but not for others to lie, because other people are not equal to one; one is superior to them. That is why one applies the double standard. However, Kant holds that all persons are equal. Hence, lying is morally wrong.

In the *Groundwork*, Kant provides another version of this argument. To treat another person as an equal is to respect her autonomy, which is her freedom to make decisions for herself. To respect another person's autonomy is to not do anything to her without her consent. Certain actions, however, are such that it is not logically possible to have the other person's consent. It is an element of the action that the person's consent is not sought, or is denied. Kidnapping is an example of such an action. Logically, one cannot consent to being kidnapped. Insofar as one consents, one is not being kidnapped, and insofar as one is being kidnapped, it is without one's consent. Such actions

are such that, necessarily, one does not respect the other person's autonomy.

According to Kant, lying is an example of such an action:

[H]e who has it in mind to make a false promise to others sees at once that he wants to make use of another human being merely as a means, without the other at the same time containing in himself the end. For, he whom I want to use for my purposes by such a promise cannot possibly agree to my way of behaving toward him, and so himself contain the end of this action.

Logically, one cannot agree to being lied to—or, more precisely, one cannot agree to being deceived by a lie. Insofar as one consents to be deceived, one is not being deceived; insofar as one is being deceived, one is not consenting to be deceived. When one lies to someone, one necessarily does not respect that person's autonomy. One treats her as less than an equal.

To return to the example of lying to get money, instead of begging someone for money, which would allow the person to make her own decision as to whether or not to lend one money, and hence treat her as an equal, one lies to the person from whom one wants to borrow money, and hence treats her as a mere means. To act toward a person in a way that precludes the possibility of her giving consent, to act toward a person without respecting her autonomy, is to treat her as a thing.

Persons, however, are not things. Persons are autonomous beings. What makes lying and deceiving morally wrong is that they are actions in which, by definition, one fails to treat a person as a person. This is true regardless of whether or not the person is harmed or benefitted from not being treated as a person. A person may benefit from being lied to because a person may benefit from not having her autonomy respected, but this does not alter the fact that, in lying to a person, one is treating the person as less than a person. Kant holds that it is always morally wrong to treat a person as less than a person.

### Objections to Kant's Arguments

There are objections that can be made to Kant's argument in the *Groundwork*. One can argue that it is possible to consent to being lied to (in

general) without knowing which lies one is to be told. For example, one can consent to being told any lie that is necessary for the throwing of a surprise party. If successful, this would establish that only lies that one has not consented to are morally wrong, and that lies that one has consented to are not morally wrong. This plausible conclusion, however, is Kantian in spirit because it is the conclusion that only lies that treat persons as equals are morally permissible.

A further objection is that lying to someone does not fail to respect that person's autonomy because the person remains free to make a decision based upon the person's lie. To return to the example of lying to get money, when one lies that one wants to borrow money, the other person remains free to decide whether or not to lend one money, even if one is going to keep the money and never return it. However, in such a case, one is treating the person in a way that one refuses to be treated oneself because one does not will to be lied to in return. Hence, in lying to someone without her consent, one does appear to be failing to respect her autonomy and treating her as less than an equal. A final objection that can be made is that, in certain situations, it is permissible to violate the autonomy of others, because they are failing to respect the autonomy of others. For example, in the case of a would-be murderer, the person may be said to have forfeited her right to have her autonomy respected, because she is intent upon murder.

In *On a Supposed Right to Lie From Philanthropy* (1797), Kant discussed the question of whether it would be a crime to lie to a would-be murderer at the door asking if one's friend was at home. Kant argued that even a lie to a would-be murderer undermines trust more generally, "although I indeed do no wrong to him who unjustly compels me to make the statement if I falsify it, I nevertheless do wrong in general by such falsification," because by lying "I bring it about, as far as I can, that statements (declarations) in general are not believed, and so too that all rights which are based on contracts come to nothing and lose their force; and this is a wrong inflicted upon humanity generally."

It is not at all clear that lying to would-be murderers undermines trust more generally, such that what everyone says is subject to suspicion.

However, if contrary to what Kant argues, such lies did not undermine trust, this still does not establish that it is morally permissible to lie to would-be murderers. This is because it has not been established that people forfeit their right to have their autonomy respected when they are failing to respect the autonomy of others. The fact that someone lies to one does not necessarily justify one's lying to her in return.

Arguments that lying and deceiving are morally wrong not merely because of their bad consequences but also because of some other reason are not necessarily arguments for why lying and deceiving are always morally wrong. It may be that lying and deceiving are morally wrong, but that they are only defeasibly morally wrong, so that, in certain contexts, they are morally permissible. First, according to Shelly Kagan, their moral wrongness may be merely *pro tanto* moral wrongness. That is, although lying and deceiving remain morally wrong, their moral wrongness may be overridden by some other moral factor, such as the moral goodness of the outcome (for example, the averting of a war).

Second, their moral wrongness may be merely *prima facie* moral wrongness. That is, although lying and deceiving remain morally wrong in normal circumstances, in extraordinary circumstances they are not morally wrong at all, because of other moral factors (for example, the people lied to are intent upon murder). Either way, lying and deceiving in certain situations may be morally permissible, all things considered. This means that even if lying and deceiving are morally wrong for reasons other than their bad consequences, they are not necessarily always morally wrong.

### Lying Versus Misleading

A final question that can be raised about the moral wrongness of lying and deceiving is whether lying is always more morally wrong than deceiving without lying, that is, misleading (or paltering), all other things being equal (that is, ignoring all other moral factors, as well as the consequences of the lie). Traditionally, lying has been judged to be more morally wrong than misleading because it necessarily involves a breach of trust, whereas deception does not. Contrary to what some writers, including Guido Mollerling, have argued, one can deceive people without

invoking trust (for example, laying a trap for a stranger in the woods). Furthermore, it has been held by Alasdair MacIntyre that in the case of lying, the responsibility for any deception lies entirely with the liar because the victim merely believed the liar, whereas in the case of being misled, the person may be in part responsible for her deceived state, because she made her own inferences to falsehoods.

Lying, according to Jonathan Adler, is supposed to be a violation of a norm of conversation that truthfulness is more important with respect to what individuals say than what they otherwise convey. However, some philosophers, including Jennifer Mather Saul, have recently argued that it is false that lying is necessarily more morally wrong than misleading, all other things being equal. Others, such as James Edwin Mahon and Cristina Ceballos, have also argued that in certain contexts people may be responsible for believing liars when they should not believe them, and that in certain contexts people may not be responsible, even in part, for being misled. Finally, it has been argued by Frederick Schauer and Richard Zeckhauser that the bad consequences of misleading may be worse than the bad consequences of lying, because misleading is more difficult to identify and is harder to penalize than lying.

## Motivational Impairment Effect

Are people more likely to succeed at their attempts at deception when they are more highly motivated to do so? In 1983, B. DePaulo, K. Lanier, and T. Davis attempted to answer this question by conducting a study to test the relationship of motivation with the success of verbal and nonverbal deception. While it would seem logical that highly motivated liars would be more successful deceivers, these researchers predicted the opposite: people who are highly motivated to deceive others would be more likely to fail than less motivated liars.

Interestingly, the study's results supported their prediction, and these researchers coined the term *motivational impairment effect* (MIE) to represent this counterintuitive finding.

### Assumptions of MIE

The logic of the MIE hypothesis is based on two assumptions. First, the MIE assumes that during face-to-face attempts at deception, most people experience heightened psychological arousal, including feelings of stress, guilt, and fear of being detected. Second, the MIE assumes a fundamental difference in people's ability to control verbal and nonverbal behavior, with nonverbal behavior being more difficult to control than verbal behavior because it is more automatic, reactive, and unintentional. According to the MIE, when potential deceivers try to mask their fear of being detected, their stressful feelings unintentionally "spill over" in the form of nonverbal cues (for example, blushing, fidgeting, and excessive perspiring) that betray their deceptive intentions.

The MIE view asserts that the increased emotional and cognitive demands of a particularly

high-stakes lie make it harder for motivated liars to avoid detection. Because there are certain automatic links between emotions and nonverbal behaviors that make them more difficult to manage, they are more likely to surface than verbal cues, even if the deceiver has spent considerable time crafting a convincing performance. Another problem with controlling nonverbal behavior is awareness; people don't typically know what their facial expressions look like to others or how others hear their voice tones. According to the MIE, the more motivated deceivers are to succeed, the harder it is for them to control nonverbal evidence of deception and appear credible to their targets. Put another way, the harder potential deceivers try to be convincing, the more likely their nonverbal behavior will give them away and make them more likely to fail.

### **MIE and Computer-Mediated Communication**

While considerable research evidence appears to support the MIE hypothesis, this research has been limited primarily to deception in face-to-face encounters. On the other hand, the logic of the MIE suggests that if the receiver is presented with only verbal information, highly motivated deceivers will be less likely to be detected. When highly motivated liars present only verbal means to their target, they should be more likely to succeed than less motivated liars. Thus, it would be in the interest of potential deceivers, particularly highly motivated ones, to limit their target's access to nonverbal cues during their presentation. Providing their potential victims with only verbal means of deception should increase their odds of succeeding.

This logic would appear to have particular relevance today as computer mediated communication (CMC) has replaced face-to-face communication as the preferred method of social interaction for most people. CMC offers deceivers visual anonymity; nonverbal and vocal "leakage cues" that may signal deception are not available to the receiver. Thus, the MIE should be attenuated or even reversed for motivated liars who interact with their targets using CMC; motivated liars using CMC should be more successful.

Proponents of the MIE hypothesis suggest this may help account for the increasing number of victims of deceptive information and practices

received through CMC channels like the Internet (for example, highly motivated pedophiles using online forums to lure potential victims). However, this advantage also exists for highly motivated law enforcement officers who use CMC to pose as children in order to locate and apprehend these and other sex offenders.

A 2005 study by M. Woodworth, J. Hancock, and S. Goorha found that liars in CMC settings were more immune to the MIE and more successful in their deceptions than in face-to-face settings. These researchers further suggested that certain features of CMC may facilitate a deceiver's success. For example, because CMC interactions are less immediate than face-to-face interactions, deceivers have more time to develop and edit their messages before transmission. Also, text-based CMC lends itself to selective self-presentation, or the ability of deceivers to intentionally select, accentuate, and present more believable self-information to their targets. These researchers coined the term *motivational enhancement effect* to describe this advantage.

### **MIE and Interpersonal Deception Theory**

While considerable research appears to support the logic of the MIE, some researchers have proposed several flaws in the MIE hypothesis. For example, using the interpersonal deception theory (IDT), J. K. Burgoon and K. Floyd challenged the MIE hypothesis, proposing that motivation often improves both verbal and nonverbal performance, and does so for both deception and truth-telling performances. The IDT asserts that deceivers strategically manage their deception through the use of various techniques that allow them to control their nonverbal as well as verbal behavior (for example, increased laughing and smiling; encouraging receivers to talk more and to answer questions first). These techniques increase the time during which deceivers can come up with believable lies and allow them to respond to receivers answers with similar answers. Furthermore, as the receivers' nonverbal and verbal cues signal their own suspicion, deceivers are able to discern these cues, adjust their own behavior, and allay suspicion.

Several studies have offered support for the IDT-based view that motivated deceivers strategically manage both nonverbal and verbal behavior, which increases their success. Burgoon

and Floyd stated, “senders who are motivated to succeed . . . can strategically manage their deceptive presentations (verbal and nonverbal) to approximate a truthful demeanor that engenders trust and evades detection.”

### Conclusion

The MIE hypothesis proposes that people who are more highly motivated to get away with their lies, compared with less motivated liars, are less likely to succeed when their targets can see and hear their nonverbal behaviors. While the MIE view has been challenged by research grounded in IDT, its logic appears to have heightened relevance for deceivers who employ 21st-century computer-mediated modes of communication.

## Movies, Lying in

What shapes individual beliefs about deception? Certainly, a variety of cultural factors exist, including family, religious beliefs, friendship networks,

romantic partners, and the media. While multiple sources compose the media, movies may represent an important source shaping individual beliefs about deception. People often seek out the movie theater as a vehicle to transport them to a different place or time, or to provide some form of escape from reality. The question that must be examined is whether movies escape the reality of the scholarship on deception.

Many movies illustrate five central themes that shape beliefs about deception. These five themes are the (1) social necessity for deception, (2) the cognitive effort associated with producing deceptive messages, (3) the difficulties associated with concealing important information from others, (4) the verbal and nonverbal cues associated with deception, and (5) the emotional reactions to discovered deception.

### Social Necessity for Deception

In 1975, Ronny Turner and his colleagues explored the idea that deception may be necessary for people to function within society. They studied people’s conversations and found that people frequently reported controlling information within conversations, and they reported several reasons for why they did so. Two of the reasons reported were that people wanted to protect themselves from being embarrassed, and that they wanted to prevent other people from being embarrassed. Turner and his colleagues argued that social reality as people perceive it would collapse if people did not control information when they communicated.

This necessity for deception to preserve social harmony is displayed in two popular comedy films about lying. The 2009 film *The Invention of Lying* explores a place and time in which everyone tells the truth, often engaging in brutal honesty, until the central character played by Ricky Gervais tells a lie in order to protect himself. This lie is followed by several others that eventually allow Gervais’s character to become a rich and famous screenwriter-turned-prophet by his ability to craft fantastical lies in a land where no one can deceive, and thus, everything is believed.

This same theme is explored slightly differently in the 1997 film *Liar Liar*, which stars Jim Carrey as a lawyer who loses his ability to lie for 24

hours after his son makes that wish on his birthday. Again, comedy arises because, as Carrey's character demonstrates, people need to be able to control information in order to do their jobs and maintain relationships.

### Cognitive Load for Deception

Both of these films demonstrate a debated topic in the deception literature: the cognitive load hypothesis. The cognitive load hypothesis suggests that it is more difficult to lie than to tell the truth because it is more cognitively taxing to produce a deceptive message. However, much of the comedy that ensues in these films is consistent with the arguments of Turner and colleagues and stands in contrast to the cognitive load hypothesis. Specifically, most of the comedy in these films stems from the difficulties and impact of people communicating in a direct and unvarnished fashion, revealing all of the thoughts that are in their heads.

Although many researchers, including Miron Zuckerman, Aldert Vrij, and their colleagues, agree with the central premise of the cognitive load hypothesis, other scholars disagree. For example, Steven McCornack and Kelly Morrison each argue that there are situations in which it is, in fact, easier to lie and more difficult to be completely honest with others. This latter notion is captured by a scene from the 2003 film *Mona Lisa Smile*, in which a character reveals that he has been lying about his past and tells his lover that she makes it very difficult to be honest.

### Deception Concealment

*Mona Lisa Smile* and several other films demonstrate the difficulties associated with a particular form of deception, namely, that of concealing information about the self from others. Furthermore, these films accurately reflect the research of Ronny Turner and his colleagues, as they illustrate the personal and social reasons for controlling information.

A variety of films fall into the concealed-identity-deception genre. In several of these films, an identity is concealed in order to protect a superhero's ability to continue to save the world, such as in the *Superman*, *Batman*, and *Spider-Man* series of movies and the animated movie *The Incredibles* (2004).

In others, comedy and poignancy arise when a character takes the identity of the opposite sex and must conceal his or her own sex. This is seen in Disney's 1998 animated movie *Mulan*, in which a daughter takes the identity of a man in order to go to war to defend the honor of her family; in the 1993 film *Mrs. Doubtfire*, in which Robin Williams takes the identity of an older English female housekeeper in order to spend time with his children after his divorce; in the 1983 film *Yentl*, in which Barbra Streisand portrays a daughter who takes the identity of a man in order to be allowed to study the Talmud; and in the 1982 film *Tootsie*, in which Dustin Hoffman's character takes the role of an older woman so he can be hired as an actress in a daytime television soap opera because nobody will hire him when he is himself.

In other films, a character portrays another person and conceals his or her true identity: Robert Pattinson, as Edward, conceals the fact that he is a vampire from Kristin Stewart, as Bella, in the 2008 movie *Twilight*; Melanie Griffith, as Tess, conceals from her coworkers that she actually is a secretary posing as her boss in 1988's *Working Girl*; Michael J. Fox, as Brantley, conceals from his coworkers that he is a mail room employee pretending to be an executive in 1987's *The Secret of My Success*. In an update of the classic Cinderella tale, Jennifer Lopez, as Marisa, conceals from an elite political candidate, portrayed by Ralph Fiennes, that she is a hotel maid in the 2002 film *Maid in Manhattan*.

A variation of the concealment theme is shown in movies in which characters lie by creating a false world, or a false reality within the real world. In the 1997 film *Wag the Dog*, Robert De Niro portrays a political advisor to the president of the United States. The president is caught in a sex scandal shortly before his re-election. De Niro hires a Hollywood producer, played by Dustin Hoffman, to manufacture a false war for the president to win in order to detract attention from the scandal. In the 1998 movie *Pleasantville*, Tobey Maguire and Reese Witherspoon portray a brother and sister who are transported to an innocent 1950s television show and must conceal the fact that they are from the future from the other characters; and in the 1998 movie *The Truman Show*, Jim Carrey portrays Truman, the

naïve star of a reality show who discovers that his entire life has been a television production.

A final variation of the deception concealment theme is the trouble and emotional difficulties that emanate from concealing important information from others over a period of time. In the 2000 film *Return to Me*, Minnie Driver portrays Grace, a young woman who has had a heart transplant. The movie relates the love relationship Grace forms with Bob, portrayed by David Duchovny. Unbeknownst to either Grace or Bob, the heart that saved Grace was the heart of Bob's recently deceased wife. Grace discovers this information and struggles with if and how to tell Bob the truth about her heart.

These concealment struggles can also be seen in the movies *Say Anything* (1989), in which John Mahoney's character James conceals from his daughter Diane (played by Ione Skye) the fact that he has been embezzling money from the

senior citizens at his senior center; the 1992 film *School Ties*, in which Brendan Fraser's character David conceals his Jewish faith from his elite schoolmates at a prep school in the 1950s; the 1993 film *Schindler's List*, which tells the story of Oskar Schindler, portrayed by Liam Neeson, who secretly saves Jews from concentration camps; the 2001 animated film *Shrek*, in which the princess character voiced by Cameron Diaz conceals from the ogre, voiced by Mike Meyers, that she transforms from a princess into an ogre each night; and the 2011 film *The Help*, in which Emma Stone's character, Skeeter, and the maids portrayed by Viola Davis and Octavia Spencer all conceal that they are writing a tell-all book revealing the perspectives of African American maids in 1960s Mississippi. All of these films illustrate the difficulty associated with concealing information, even when it is for protective personal reasons or for the greater good.

Israeli President Ezer Weizman (center) and Prime Minister Yitzhak Rabin (left) join director Steven Spielberg (right) at the Israeli premier of his movie *Schindler's List*, March 3, 1994. The film tells the story of Oskar Schindler (played by Liam Neeson), who secretly saves Jews from concentration camps. The storyline depicts a variation of the deception concealment theme: the trouble and emotional difficulties that emanate from concealing important information from others over a period of time.

### Behavioral Cues to Lying

Another deception theme portrayed in the movies is the idea that people can tell when others lie because of certain behaviors that accompany deception. These accompanying verbal and nonverbal behaviors are known as deception (leakage) cues. For example, in the 1995 film *The American President*, Annette Bening plays a character who falls in love with the current president of the United States, portrayed by Michael Douglas. In one of their early encounters in the film, Bening informs the president that she knew he had left something out of a speech she had attended because he did something with his face. Later in the film, she is skeptical about something he says because he is doing that thing with his face again. In the 2006 film *Casino Royale* from the James Bond series, Agent 007, portrayed by Daniel Craig, reveals the poker “tell” of the villain: whenever he bluffs he holds the corner of his eye.

The idea that people leak cues when they deceive is more scientifically portrayed in the 2003 film *Runaway Jury*. In this film Gene Hackman portrays a strategic legal consultant for gun manufacturers who are being sued. In the scenes revealing the jury-selection process, the audience sees how experts use computers and video imagery to identify when people are lying.

Eye contact is an example of a nonverbal behavior that is assumed to be related to deception. People tend to think that during the actual act of deception, a person cannot look another in the eye and simultaneously lie to his or her face. This is illustrated in the 2006 film *The Last Kiss*, with the dialogue “Look me in the eye and tell me that you don’t love me anymore,” followed by the statements “I don’t love you anymore,” and “I refuse to accept that.”

While many people may assume that lack of eye contact indicates deceptive behavior, research suggests that eye contact does not indicate whether or not someone is lying. Simply put, a person can look another in the eyes and lie right to his or her face, as illustrated by a scene from the 1988 movie *Dangerous Liaisons*. In this film, the Vicomte de Valmont (portrayed by John Malkovich) breaks off his affair with Madame Marie de Tourvel (portrayed by Michelle Pfeiffer), despite the fact that he is in love with her. He appears

bored and nonchalant, discussing reasons for dissolving the relationship that were beyond his control. She collapses in anguish while he continues to matter-of-factly lie to her face.

There is disagreement in the field regarding the concept that deception is associated with leakage cues because it is so arousing. On one side of the debate are scholars, such as Paul Ekman and Miron Zuckerman and his colleagues, who argue that because deception is arousing, multiple cues are associated with it. On the other side of the debate are scholars such as Bella DePaulo and Siegfried Sporer who with their colleagues each argue that relatively few cues are linked with deception. In a recent summary of the literature, Siegfried Sporer and Barbara Schwandt found that only two of the nine behavioral cues analyzed were associated with deception: when people deceive, there is a change in vocal pitch and a longer pause before they lie.

### Reaction to Discovered Deception

A final theme illustrated in some movies is the idea that when people, especially women, discover deception they take it in stride by forgiving the other person in a short amount of time, rather than becoming emotionally devastated. As shown in the 1987 movie *Overboard*, Dean Profit (portrayed by Kurt Russell) takes advantage of Joanna Stayton (portrayed by Goldie Hawn) after she falls overboard from her yacht and develops amnesia. Dean convinces her that they are married and that she is the mother of his four children. She becomes the wife, mother, and maid to his unruly family. At the end of the movie he reveals his deception. She attempts to go back to her life on the yacht but ultimately gives it up for the love of the man who deceived and took advantage of her.

As seen in the 1998 film *You’ve Got Mail*, Joe Fox (played by Tom Hanks) spends the better part of the film lying to Kathleen Kelly (played by Meg Ryan) by concealing the fact that he is the owner of the retail giant bookstore that put her little bookshop out of business. At the end of the film he reveals his true identity to her, and she readily accepts his deception in exchange for his love. This theme also is seen in the 2000 film *What Women Want*, starring Helen Hunt as an advertising executive who forgives Mel Gibson

from sandbagging her at work and getting her job after an accident leaves him with the ability to hear women's thoughts. Like the other movies, the film ends with the deception revealed and the happy couple in each other's arms.

Notably, the research on emotional reactions to discovered deception done by Steven McCornack and Timothy R. Levine indicates a different picture. People respond emotionally to the knowledge that others have lied to them, and women tend to respond more negatively than men.

## Myth

Myths are traditional or legendary stories, usually concerning a being, hero, or event, often involving deities or demigods, and explaining some practice, rite, or natural phenomenon. Joseph Campbell outlined four fundamental functions of myths: the mystical function (inspiring awe), the cosmological function (describing the nature of the universe), the sociological function (supporting or validating certain social orders), and the pedagogical function (providing models for living).

Deception is widespread in myth, especially for the sociological and pedagogical functions. Myths vary cross-culturally and temporally but possess similar human-oriented deception themes. Carl Jung claimed examining myth and its universal nature helps people infer existing "archetypes" originating from the collective unconscious and composing part of people's psychological lives, guiding emotions and experiences, and acting as prototypes of people, personalities, or behaviors. An example is the trickster, a crucial character in many deception myths. Other common themes include marital affairs, power struggles, displays of cleverness or wit, and teaching lessons. Myths teach people about human nature and how to navigate their social worlds.

Myths themselves could be considered deceptive, as they are often represented and transmitted as truths and sometimes sanctioned by people like rulers or priests possessing deceptive agendas related to power or impositions of moral or lawful order. Myths were once transmitted orally, allowing transmitters to tweak details to suit their own purposes. The conception of poets—oral and written transmitters of myth—as liars is timeless, and poets like Homer or Ovid could control

audiences and validate certain social orders with the framing of their stories. Upon the advent of writing, the ability to record myths allowed for greater concretization of details and wider transmission, which may have made deception more difficult in the retelling of myths.

Poets are not the only liars. Parents use myth to teach children lessons or morals or to unite families via cultural expression; however, parents may deceive children by not revealing myth's fictitious nature. Examples include Aesop's fables, over 600 stories mainly about anthropomorphized animals illustrating how to live, which are replete with deception, and cultural myths like Santa Claus and the Easter Bunny. Some argue such parental deceptions are harmful to child development, but others argue they are a necessary part of growing up.

### Self-Deception

Self-deception is a common theme in myth. Such stories illustrate folly resulting from thoughts, feelings, or rationalizations incongruent with reality that lead protagonists to exhibit morally negative attributes. One human example from Greek myth is Narcissus, an arrogant hunter famous for his beauty, who deceived himself that what he saw in a pool of water was someone he could love more beautiful than himself, when actually it was his own reflection. He could not relinquish this fantastical, "narcissistic" love and eventually died at the pool. Another example is King Midas, who greedily deceived himself into thinking riches, and the appearance they allowed, were all he needed to make him happy. Dionysus, god of decadence, gave Midas the power to turn anything to gold simply by touch. Midas was overjoyed initially, but when his feast and his daughter turned to gold he realized his folly and gave up his power.

A fiery fate befell Greek demigod Phaethon, son of Helios the sun god, who because of his desperation to prove his godly birth exhibited hubris, deceived himself that he could control the sun chariot, and almost burned up the world. The demigod Achilles, the Trojan War hero in Homer's *Iliad*, also believed himself invulnerable. His egoistic self-deception bested him when Paris, the prince of Troy, shot him in the heel, his one vulnerable area his mother failed to make immortal when dipping him in the river Styx.

Achilles died still believing he was indestructible. All these instances of self-deception mirror and address real-world social or personality blunders involving flaws related to overconfidence, greed, or desire to preserve one's self-presentation being manifest when characters lose contact with realistic expectations.

### Dyadic Deception

Deception in myths frequently occurs in dyads, or pairs. Instances of dyadic deception include marital affairs, power struggles, and demonstrations of cleverness.

Mythical marital spats are often exaggerated versions of reality, with serious costs associated with deception. Lessons portrayed sometimes appear designed to deter real-life domestic upsets, but others are more cynical. When demigoddess Helen is unhappy with her husband, King Menelaus of Sparta, her affair with Paris initiates the Trojan War. Agamemnon, king of Mycenae, deceives his wife Clytemnestra into bringing their daughter Iphigenia to Aulis to wed Achilles. He instead sacrifices his daughter to the goddess Artemis because a seer told him that if he failed to do so, Greek ships could not sail to Troy. When Agamemnon returns victorious, Clytemnestra welcomes him lovingly, only to trick him into taking a relaxing bath and then murdering him in the tub. Such stories discourage marital deception.

Gods in myth are also famous for deceiving each other via extramarital affairs, both with other gods and with humans. In her affair with Ares, Aphrodite continuously deceived Hephaestus until he discovered and trapped the lovers in an unbreakable net during a tryst, dragging them to Mount Olympus—the gods' abode—to display and shame the pair. Zeus and Odin—kings of the Greek and Norse gods, respectively—also frequently cheated on their wives Hera and Frigg with mortal women, other goddesses, and even other Titans or giantesses. To avoid detection, Zeus appeared to mortal females in disguise and deceived them about his identity, masquerading as such entities as a swan, the virginal goddess Artemis, and a shower of golden rain.

Dyadic power struggles also often involve deception in myth, mirroring real-world interpersonal disputes and challenges to authority. Prometheus the Titan tried to cheat Zeus out of

his rightful traditional sacrifice. Hades, always jealous of his brother Zeus, deceived his sister Demeter, and with Zeus abducted her daughter Persephone so that she could be his bride in the underworld. Demeter recovered Persephone, but only after Persephone was tricked into spending one-third of every year in the underworld as Hades's wife. The Egyptian god Seth also envied his brother Osiris, king of the gods, and hated his sister (Osiris's wife) Isis. Seth wished to kill Osiris and be ruler. So he devised a plan, learning of Osiris's exact measurements and constructing a beautiful chest that would fit only him. He threw a feast for Osiris and deceived him by proclaiming that whoever fit into the chest could keep it. Osiris succeeded, but Seth sealed him inside and killed his brother's human form.

Mythical characters also deceive one another to demonstrate cleverness. The clever trickster is a prime example of a deception-relevant Jungian archetype and in myth is represented as a god, human, animal, or other creature that deceptively plays tricks or tends to break the rules or norms of behavior. Tricksters can be sly, foolhardy, or both, often thwarting traditional morality or rules of the gods and/or nature. They are usually funny, may evoke feelings of discomfort regarding transgressions, and throughout history have been predominantly male. Their stories often provide moral lessons for audiences of the nature that "bad things happen when you deceive."

One prominent example of a trickster from West African folklore is Anansi, the spider god. Many Anansi myths concern his efforts to deceive people into letting him steal resources that can benefit him, or tricking females into having sex with him. However, his tricks usually go awry and harm him and benefit others, as when he tried hoarding all the world's wisdom for himself and accidentally let it wash away into the ocean, where it spread among everyone. Coyote is a similar trickster found in western Native American cultures. With the ability to transform his shape, Coyote often tricks people, but ultimately gets caught and appears foolish in the end. Like Anansi, Coyote can be mean but also noble, sometimes even playing the Robin Hood figure, a when he stole water from the water-wealthy Frog people because they were greedy.

A famous example of a human trickster demonstrating his cleverness is Odysseus from Homer's the *Odyssey*. Traveling from Troy to Ithaca, Odysseus deceives nearly everyone he meets in order to return home safely but also to prove himself a resourceful, clever individual. The trickster Odysseus deceived the Cyclops Polyphemus during his travels by first cleverly concealing his identity (calling himself "Nobody") and then blinding the Cyclops and escaping from the cave in which he was imprisoned with his men under the bellies of Polyphemus's flock. Athena also cleverly deceived Odysseus multiple times throughout the *Odyssey* and tested Odysseus's own cleverness to keep him confident, as when she masked the landscape of Ithaca and disguised herself as a shepherd upon Odysseus's homecoming.

Often people view such trickster figures as culture heroes who change the world through innovation and creative solutions, paralleling the human predicament that while deception may normally be disapproved of, its results are often venerated. Other examples of important trickster figures include Loki (Norse); Prometheus (Greek); the god Hermes (Greek) or Mercury (Roman); Pan (Greek); Br'er Rabbit (African American); Iktomi, the spider spirit (Lakota Native American); Raven (Native American Pacific Northwest); Baba Yaga (Russian); the spirit Ellegua (Yoruba); and the monkey king, fox, and frog (Chinese).

In Norse myth, knowledge is power, and Odin frequently uses deception to acquire knowledge from wise men. In *Vafþrúðnismál*, Odin sought wisdom from the giant Vafþrúðnir by challenging him to a contest while in disguise, the prize purportedly being his life. However, Vafþrúðnir unwisely wagered his own head. Odin revealed himself to the giant by asking him a question only Odin would know the answer to and thus won the bout. In *Þrymskviða*, the giant Þrymr steals the god of strength Thor's hammer, Mjólnir, and demands Freyja, Norse goddess of love, as ransom. Mighty Thor cross-dresses as Freyja to trick Þrymr, get the hammer back, and smite him.

All these instances of mythic deception illustrate deceptive themes from everyday social life in a hyperbolic manner—much like soap operas today—and guide people (impartially or not) in navigating their social environments.

### Group Deception

There also exist many instances of mythic deception at the group level involving love, war, and mischief-making power struggles. For example, before Paris wooed and “kidnapped” Helen from Sparta, he convinced the Greeks he was on a diplomatic mission. In another example, Odysseus concealed his identity from his wife Penelope and her host of suitors upon returning to Ithaca. With the help of Athena, he returned appearing much weaker than he actually was, which allowed him to infiltrate his home, kill his wife’s suitors, and reclaim his court and family.

One of the greatest instances of mythic group deception involves the Trojan horse. After 10 years of failed siege, the Greeks built a giant wooden horse and hid men inside it. They then pretended to sail away, and the Trojans saw the “peace-offering gift” of the horse as a victory trophy and brought it into Troy. At night, the Greek soldiers emerged and opened the gates for the rest of the Greek army that had sailed back under darkness. The Greeks destroyed Troy, and this act of deception won the war.

Often myths of this variety teach lessons. When pirates attempted to kidnap young Dionysus, they tried to deceive him, saying they would sail him to his destination. However, clever Dionysus pretended to play along when they were going in the wrong direction, and he even feigned helplessness. When the pirates began mocking him, Dionysus revealed his true form and transformed them all into dolphins. This myth teaches audiences about the punishments that can come from bullying mistreatment. In another example, Prometheus deceived the gods and stole their fire for humans. Zeus harshly punished this disrespectful deception by chaining Prometheus to a rock, where his liver was eaten daily by an eagle and regrown every night.

Group-level deceptions involving power struggles frequently occur in Norse mythology. Icelandic sagas are replete with family feuds and property disputes. One story describes a trip by Thor, his servant, and Loki to Jotunheim, land of the giants. While there, they were deceived by ruling giant Utgard-Loki into thinking they failed at simple feats, including an eating contest, a race, drinking from a horn, lifting a cat, and wrestling a crone. This disheartened them, especially Thor.

They were informed upon departing that they were actually contending with the entities Fire, Thought, the Sea, the Serpent surrounding the world, and Old Age, respectively, and that they were formidable challengers.

Finally, the Norse gods—the *Æsir*—hired a builder to secure Valhalla, home of the gods, in exchange for the goddess Freyja, the sun, and the moon. The *Æsir* agreed but specified that the builder must finish within three seasons unassisted. The gods deceived the builder, giving him an “impossible” task. The builder requested only the use of his horse Svaðilfari, and the trickster god Loki convinced the others this would be fine. However, the builder also deceived the *Æsir*, as Svaðilfari was enormously powerful. The builder made rapid progress, and the *Æsir* blamed Loki and demanded he save their scheme or be killed. Loki delivered more deception by transforming himself into a mare and seducing Svaðilfari, distracting the stallion enough to delay building. When the gods discovered the builder was a disguised giant, Thor smote him.

### Universality of Mythical Themes

Deceptive themes are found worldwide and across cultures, as seen with the trickster archetype. What accounts for such convergence? One possible explanation is cultural transmission. The Romans borrowed much of their pantheon from the Greeks. However, many similar stories have arisen in drastically different places that did not interact in a less globalized world.

An alternative explanation involves something similar to Jung’s idea of the collective unconscious. Michelle Sugiyama asked how, without writing, ancestral humans stored and shared information. Her research suggests that narrative may have evolved as a psychological adaptation for that purpose. Oral traditions of hunter-gatherers contain much information regarding recurring problems of forager life, like deceiving or being deceived by others, resource acquisition, predator avoidance, cheating, and way-finding. Narrative may have served to help make people aware of these survival issues, perhaps thus explaining the ubiquitous presence of certain themes. For instance, deceptive cheaters would have posed a significant threat to a group’s well-being by reaping benefits of cooperation, such as food gathering, while failing to

contribute. This may have led to stories showing deceivers being caught or punished. Alternatively, sometimes deception would have been useful for navigating one's social environment: hence, deception stories involving demonstrations of cleverness.

Whatever the origin, it seems deception has played a major role in myth for thousands of years, and some common themes of deception teach people about themselves and their social worlds.

## Napoleon Bonaparte

Napoleon Bonaparte (1769–1821) was born in his ancestral home of Casa Buonaparte, at Ajaccio, Corsica, on August 15, 1769. He was the second son of Carlo Maria di Buonaparte and Maria Letizia Ramolino. His family, undistinguished minor Italian nobility, had moved to Corsica in the 1500s. His birth came a year after the Republic of Genoa had transferred Corsica to France. Christened with the Italian name, Napoleone di Buonaparte, he eventually Gallicized it to Napoleon Bonaparte.

Napoleon's father, Carlo Buonaparte, was a lawyer and Corsican political activist. After France took control of Corsica in 1768, he opposed the French accession and joined other Corsican patriots in the mountains. However, seeing better opportunities in cooperating, he accepted French rule and was eventually a representative to the Court of Louis XIV from Corsica. He may have passed on some diplomatic skills to his son Napoleon, as well as Corsican duplicitous folklore and proverbs about lying (e.g., "lies have twisted limbs").

Carlo Buonaparte, an aristocrat, secured admission at royal expense (*boursiers*) for Napoleon in the school at Brienne. Entering at the age of 10, Napoleon concentrated on mathematics, geography, and history. He completed his studies ahead

of schedule, at the age of 15. He next entered the École Militaire in Paris, again on a royal scholarship. At the age of 16, he was commissioned first lieutenant in an artillery regiment. Shortly afterward, his father died. He gained leave to go to Corsica to deal with family's affairs. To extend his military leave, he deceitfully sent his commanding officer a medical certificate stating that he was ill and unfit for duty. He then went to Paris to secure payment of 9,000 francs owed his father. There, he unsuccessfully struggled with the government and learned much about bureaucracy's red tape. He then returned to his regiment.

### French Revolution

When the French Revolution began, Napoleon was uninvolved until the National Assembly was organized. He then adopted the ideas that the revolutionaries advocated and sailed to Corsica to spread the Revolution; however, he was ordered to return to duty. To stay in Corsica, he engaged in blatant fraud to win election to the rank of lieutenant colonel of Corsican volunteers. His dishonesty was matched by other coup d'états in the future. However, he was not able to win support for his agenda, and he endangered his family, who were forced to escape to France.

Napoleon found an opportunity to demonstrate his military skills during the siege of Toulon. His fame spread with the city's capture. For

*Napoleon Crossing the Alps (1801), a painting by Jacques-Louis David, captures the leader's valiant skills during his military career, which he entered at age 16. He advocated deception as a military strategy, exaggerating troop numbers and utilizing spies, secret codes, and media propaganda.*

the rest of his life, his fame rose and fell with his success and failure in the events of the day. The event that next propelled him into the forefront was the ending of the National Assembly in favor of the Directory. To protect itself from the mobs in Paris, the Directory called upon Napoleon for help. He calmed the situation with a “whiff of grapeshot.” The Directory promoted Napoleon to second in command of the Army of the Interior.

In 1796, Napoleon married Josephine (Rose de Beauharnais). He was dispatched a few days later to northern Italy to fight the Austrians. His Italian campaign ended with a treaty in 1797. In 1799, he was ordered by the Directory to campaign in the Near East. He conquered Egypt, and would have been successful against the Ottoman Empire, if the British had not destroyed the French fleet at Aboukit. About this time, Napoleon learned that the situation at home was unstable. He quickly

returned to Paris, where he successfully maneuvered to become the first counsel, and soon thereafter took sole power.

To please the Paris mob, he allowed the return of the émigrés (including aristocrats), and reestablished Roman Catholicism as the religion of France while providing protections for other faiths. He also reformed the French administration and its national finances. By 1805, a new French code, the Civil Code, often called the Napoleonic Code, was issued. Numerous other reforms were instituted that strengthened France.

### Exile

Between 1805 and 1807, Napoleon used the newly formed Grande Armée to establish dominance in Europe. Unable to bring the British to terms because of their naval superiority, he closed continental Europe to the British “nation of shopkeepers.” However, smuggling spread so that British goods flowed into Europe, especially through Russia. In 1812, he launched a Russian campaign that reached Moscow but was defeated by the Russian winter and the Russian defense through a scorched earth strategy that deprived the French of supplies acquired by foraging.

Returning to Paris defeated and with the British advancing in the Iberian Peninsula Campaign, Bonaparte struggled to stay in power from 1813 to 1814. He finally abdicated and went into exile on the Island of Elba in the Mediterranean. In 1815, he escaped from Elba and returned to France where he sought to regain the throne. However, the Congress of Vienna outlawed him and forced him to fight for survival. He organized a new army and advanced into Belgium, where he was defeated by the Duke of Wellington at the Battle of Waterloo. He was forced to abdicate and was exiled to St. Helena. There, he was able to walk about the grounds of the house where he lived while dictating his memoirs. He died in 1821 of stomach cancer.

Napoleon advocated secrecy to protect military movements. He also advocated deception, once telling General Clarke to tell his brother Joseph, King of Spain, to exaggerate the number of troops he had or that the enemy had. He used examples from different campaigns against the Austrians and others as illustrations. He encouraged orders of the day to be exaggerated in order to encourage

the troops and to discourage the enemy. He also advocated using disinformation to fool spies and the enemy.

Napoleon used spies and secret codes to gain information. He used the press and created propaganda to gain favorable public opinion. He was a master of propaganda, even lying or exaggerating to promote morale. He issued carefully crafted bulletins, dispatches and proclamations full of distortions to win public opinion. The French expression to “lie like a bulletin” (military information sheet) dates from this period. Information favorable to Napoleon and designed to awe the French public was at times inserted *ex post facto*. He also used military medals, art, and theater as propaganda tools.

Napoleon was a serious student of history, especially of great commanders, claiming that “History is a set of lies agreed upon.”

## Narcissism

Narcissism is a personality trait that is associated with several kinds of dishonesty. Most of these dishonest behaviors can be described as self-directed or other-directed, although some seem to involve dishonesty toward both the self

and others. When narcissists, or people who are unusually egotistical, tell lies directed toward other people, these lies are often in the service of narcissists' personal, even selfish, goals. When narcissists' lies are directed toward themselves, the lies also serve a selfish end. Narcissists lie to themselves about their abilities, characteristics, and behaviors in order to build and maintain their grandiose self-images.

Several decades of research have described the nature of narcissism and its associated characteristics. Narcissism lies on a continuum, which means that some people are relatively low in narcissism, some people are relatively high, and most people are somewhere between the two extremes. Narcissists, or people who are relatively high on the continuum, hold exaggerated self-views and see themselves as superior to others. They tend to feel entitled to special treatment. Narcissists are generally extraverted, highly sensitive to rewards, and prone to thrill-seeking, but also disagreeable, domineering, arrogant, and impulsive. Narcissists tend to become hostile when they are challenged, and when they learn about others' successes, they tend to feel envious. In their own quests for success, narcissists are prone to taking unfair advantage of others.

In some ways, narcissists seem highly motivated. Narcissists generally seek dominance, fame, uniqueness, power, wealth, and others' admiration. Sometimes they achieve these ends (for example, some accomplished athletes and celebrities seem to be highly narcissistic), but most narcissists are no more successful than the average person. In domains concerned with getting along with others, narcissists tend to be less motivated than average. Narcissists are less interested than most people in understanding others' feelings, cooperating with others, or working toward others' well-being.

On the Narcissistic Personality Inventory, a widely used questionnaire that measures narcissism, men generally score a little higher than women. However, biological sex does not correlate as strongly with narcissism as masculinity does. Toughness, independence, dominance, and risk-taking are considered key characteristics of masculinity (and are also characteristics valued by narcissists), so it is understandable that narcissism is more strongly associated with masculinity than

biological sex. Narcissism is also weakly associated (in a negative direction) with femininity.

Age is negatively related to narcissism, such that adolescents score higher than younger adults, who in turn score higher than older adults. The negative relationship between age and narcissism may be due to either developmental changes, cultural changes, or both. In recent decades, Western cultures have tended to strongly emphasize a focus on the self, and among American college students, scores on the Narcissistic Personality Inventory have steadily risen since the early 1980s. This latter finding suggests that an increase in cultural messages that emphasize the self at least partly explains why younger people tend to be more narcissistic than older people.

When a person is so high on the narcissism continuum that his or her behavior causes significant distress (to the self or others), or increases the risk of suffering, that person may qualify for a diagnosis of narcissistic personality disorder. Some authors have suggested that narcissists may become distressed and qualify for a diagnosis when their needs (for glorious success, fame, and so on) are repeatedly frustrated. If their own distress does not motivate them to seek treatment, narcissists may enter treatment because of pressure from distressed friends or family members. Narcissistic personality disorder is considered difficult to treat, but recent research has documented some successful psychotherapeutic approaches.

There is currently controversy about how narcissistic personality disorder differs from other personality disorders. As the American Psychiatric Association developed the fifth edition of the *Diagnostic and Statistical Manual for Mental Disorders*, researchers debated the usefulness of narcissistic personality disorder as a concept. The status of this disorder may be debated well into the future, but one point of relatively clear agreement is that some people behave so egotistically that they cause problems not only for themselves but also for people around them. Narcissistic people can be annoying, hurtful, and sometimes even violent.

### **Narcissism and Other-Directed Deception**

Evidence suggesting that narcissism is related to behaviors aimed at deceiving others is mostly indirect. Investigations of the association between

narcissism and lying are lacking, but many studies show that narcissism is related to characteristics and habits that are associated with lying. Because research on personality traits is correlational, it is not always clear whether narcissism (or some other trait associated with narcissism) causes dishonest behavior. Nevertheless, many studies suggest that lying is more common among narcissists than it is among people who are low in narcissism.

Research has established that a variety of problem behaviors that typically involve lying are related to narcissism. Some of these problem behaviors include pathological gambling and compulsive buying, two habits that often involve lying about frequency of engaging in the behavior and financial losses. Other problem behaviors associated with narcissism include heavy alcohol use (which often involves lying about frequency of use) and infidelity (which often involves lying to at least one partner). This pattern of associations does not directly link narcissism to lying, but it suggests that such a link is likely.

Stronger evidence of a link between narcissism and lying comes from studies showing that narcissists seem to have little hesitation about describing themselves as relatively dishonest (and generally unethical) on questionnaires. Several versions of the Narcissistic Personality Inventory include the statement, "I can make anybody believe anything I want them to." This statement is probably frequently endorsed by people who think they are good liars, and when it is endorsed, it contributes to a higher narcissism score.

Narcissists also score relatively high on questionnaire measures of Machiavellianism, a trait that involves manipulating and deceiving others. They also score highly on self-monitoring, a trait that involves a chameleon-like tendency to present oneself differently in different social situations, and psychopathy, a trait that involves anti-social behavior coupled with diminished feelings of empathy and guilt. Moreover, on a questionnaire that personality psychologists use to assess honesty and humility, narcissists tend to receive relatively low scores.

### **Narcissism and Self-Directed Deception**

Narcissists are not only dishonest with others but also are often dishonest with themselves. Several studies suggest that narcissists tend to cheat on

tests. Normally cheating on tests is considered to be other-deception (because it is an attempt to deceive an authority figure about one's skill), but for narcissists in some circumstances, cheating on tests may also involve self-deception. One recent study showed that narcissism is related to rationalized, but not deliberative, cheating. Deliberative cheating is intentional and recognized as wrong, whereas rationalized cheating involves explaining misconduct to oneself in a way that makes it seem morally acceptable. The link between narcissism and rationalized cheating suggests that, at least some of the time, narcissists' dishonesty toward others is facilitated by narcissists' dishonest, internal rationalizations of their own behavior.

Narcissists' exaggerated self-views also seem to be self-deceptive. Life usually provides people with a balance of positive and negative feedback, but in many of their self-descriptions, narcissists seem to emphasize their strengths much more than their weaknesses. Several studies suggest that narcissists rate themselves high in intelligence, attractiveness, and performance in group tasks, even when objective evidence does not support these self-perceptions. Narcissists also claim to have greater general knowledge than they actually do. On some personality traits, narcissists see themselves as better than the average person, and better than their romantic partners. The latter finding is especially interesting because many people in relationships view their romantic partners at least as positively as, if not more positively than, they view themselves.

One interesting theme in narcissists' exaggerated self-views is that they are more likely to consider themselves superior on social dominance characteristics (associated with getting ahead) than social connection characteristics (associated with getting along). In some studies, narcissists have rated themselves as better than the average person in mind-reading ability (during a business negotiation) and also better than average in intelligence and extraversion. They do not rate themselves as better than average in morality or kindness. Findings like these suggest that narcissists are at least somewhat selective with their exaggerated self-perceptions.

Narcissists tend to explain their successes and failures in ways that probably sustain their exaggerated self-perceptions. Research suggests that

when narcissists are told they have performed well, they explain their success primarily in terms of personal ability. Attributing success to personal skill, of course, helps sustain a grandiose self-image. When narcissists are told they have performed poorly, they explain their failure in terms of external circumstances (such as attributing a low test score to extreme test difficulty). By blaming poor performance on external circumstances, narcissists can protect their grandiose self-images from countervailing evidence. The flexibility narcissists allow themselves when explaining successes and failures suggests that narcissists are often dishonest with themselves when thinking about performance feedback. After all, whether the outcome is success or failure, a full and honest explanation for one's performance should typically include consideration of both personal abilities and external circumstances.

## Native Americans

The traditional history of American Indians suggests that the massive loss of life by native peoples after 1492 was both tragic and unavoidable and was not intended by the incoming settlers from Europe. However, since the Vietnam War era, a strong counter-narrative has developed specifying that the native population was intentionally and drastically reduced by means of an American Indian holocaust. In forthright language, the new narrative charges that deception and lies were at the heart of the traditional history.

The traditionalist argument is that Indians' resistance to European diseases was low, and many fell mortally ill because of that cause. The deaths, though unfortunate, were part of the price paid for progress as Eurocentric ideas and ways of life spread westward. In this traditional view, the Indians were depicted as living in small, scattered bands of hunting and gathering tribes in North America, leading a miserable existence until the advanced culture of the settlers came along to show them a better way of life.

Waves of historians and anthropologists gave legitimacy to this line of thought by claiming that the original aboriginal population was not nearly as large as some had suggested, and that the main cause of death was disease and not warfare. Further, these historians maintain, it was inevitable there would be some reduction in population on both sides of the conflicts over land. The vacant geographic area now known as the United States was open to whoever might wish to claim it; claims to land could invite challengers. Jews and Jewish scholars also lent their collective voices to legitimize the narrative by arguing that upstart claims of an American Indian holocaust were

overdrawn and inaccurate. They cited the exclusivity of the Jewish holocaust, noting that all of the other claims of genocide pale in comparison with the tragic loss of life in the Nazi concentration camps in Germany during World War II.

In the counter-narrative, holocaust writers state that the idea of "no American Indian holocaust" is one of the biggest lies ever foisted upon the worldwide public about American Indians. Several holocaust scholars have pointed out the scope of this deception. Ward Churchill, for example, contends that during the 400 years from 1492 to 1892, the Indian population was reduced from approximately 125 million to less than one quarter of a million, a reduction of about 90 percent. The causes of death were disgusting, barbaric, and unfathomable to the modern reader. The same scholars that bring evidence of these horrific deaths also unashamedly indicate that failure to recognize the carnage as genocide amounts to a denial of the American Indian holocaust, a lie that flies in the face of the statistics they provide.

These writers contend that the "outrageous" massacres during the Indian Wars, such as those at Sand Creek and Wounded Knee, were simply continuations along a steady path of genocide, and were not anomalies as the standard narrative suggests. At Sand Creek in 1864, a 700-troop force of Colorado militiamen attacked and destroyed a village of friendly Southern Cheyenne and Arapaho encamped in southeastern Colorado, killing and mutilating an estimated 148 Indians, more than half of whom were women and children. By the end of the following year, the Cheyenne and Arapaho had been driven out of Colorado. This violence warranted national attention as Congress convened hearings to investigate the use of excessive force.

The Wounded Knee conflict in 1890 reportedly began with a fight between an Indian and a soldier, which escalated into the indiscriminate shooting of 150 Lakota Sioux, including scores of women and children, by the U.S. 7th Cavalry Regiment. Comparable massacres of American Indians at Washita River (Oklahoma), Blue Water Creek (Nebraska), Sappa Creek (Kansas), Bear River (Idaho), and Camp Robinson (Nebraska) are cited as evidence of the regularity of such killings.

Ward Churchill, David Stannard, and others have written that the slaughter of Indians at places like Sand Creek and Wounded Knee were only the beginning of the genocide, because it embraced only one type of genocide, namely, physical extermination. Working closely with the definition of genocide developed by Raphael Lemkin (and later, the United Nations), Churchill's view was that biological and cultural genocide occurred along with the physical type. Biological genocide included acts such as involuntary sterilization, compulsory abortion, segregation of the sexes, and obstacles to marriage, as well as any other policies whose purpose was to prevent births within a target group.

Cultural genocide encompassed the idea of denationalization and imposition of an alien national pattern, which was introduced into the genocide dialogue by Lemkin in 1944. Cultural genocide includes all policies aimed at destroying the specific characteristics by which a target group is defined, or defines itself, thereby forcing it to become something else. Among the acts specified are the forced transfer and systematic exile of individuals representing the culture of the group; the prohibition of the use of the national language; the systematic destruction of books printed in the national language; and the destruction or dispersion of objects of religious, artistic, or historical value. Thus, the forced removal of tribes east of the Mississippi River during the Trail of Tears in 1838, and the removal of Indian children from tribes for relocation to Indian industrial schools are two examples that fit Churchill's definition of cultural genocide.

Similarly, the overthrow of the Kingdom of Hawai'i in 1893 paved the way for a provisional government friendly to the United States and led to the gradual erosion of native Hawai'ian culture. A less violent but still potent land grab in the Alaska Native Claim Settlement Act of 1971 transferred native land rights to a series of Alaskan Native regional corporations, in the process nearly extinguishing the native heritage, culture, and way of life of the Eyak tribe.

This preliminary definition of genocide developed by Lemkin was later revised and distilled into the second article of the 1948 Convention on Prevention and Punishment of the Crime of Genocide. It defines the crime as being any of the following acts committed with intent to destroy a religious,

ethnic, or national group: (1) killing group members, (2) causing serious mental or physical harm to group members, (3) purposefully changing the group's conditions of life with the intent of destroying the group, (4) imposing measures to prevent births within the group, and (5) under threat of force, transferring children of the target group. Churchill noted that killing is one of five criteria, or 20 percent of the total. The other four, or 80 percent of the total of the definition of genocide posited in international law, consist or devolve upon explicitly nonlethal lines of action.

### COINTELPRO

In the 1960s, when the American Indian Movement (AIM) began to advocate more openly for the holocaust position and for Indian self-determination, its members were cast as political extremists bent on overthrowing the U.S. government, and as a result, were subjected to a Federal Bureau of Investigation counterintelligence program called COINTELPRO. The purpose of this program was to interfere with the political activities of groups deemed harmful to the United States, and to seek the destruction of the groups "from within" by disrupting them and/or causing the groups to violate the law. COINTELPRO actions against AIM led to the arrest of the organization's key leaders from 1968 to 1975. Further, there was a serious allegation that the program's actions against AIM in 1975 advanced into a counterinsurgency, in which scores of Indians died in and near the site of the 1973 Wounded Knee siege.

The traditional narrative lives on and continues to be a viable explanation for reductions in the native population. Experts with access to all the statistics disagree about the size of the original population of natives at the time Christopher Columbus arrived in the New World. Additionally, Jewish scholars have pushed back against the use of the concept of genocide as a heuristic tool to analyze the Indian experience. They are probably right in arguing that, no matter what atrocities American Indians faced, their experience was not comparable to that of the European Jews in Nazi concentration camps and ghettos during World War II. Thus, use of the term *genocide* may be an overstatement. Critics also claim there was a distinct lack of genocidal intent in many of the instances of massacres cited by

Churchill, Stannard, and others. Finally, in 2006, Ward Churchill was accused of academic misconduct, including fabrication and plagiarism, thus besmirching the totality of his work.

Despite this, the counter-narrative appears to be gaining ground and emerging stronger each year as an explanation of the historical experience of the American Indians. As multiculturalism spread on college campuses during the 1990s, students were familiarized with the holocaust argument, and many read it in the native voice. The counter-narrative was further legitimized by the current understanding that the Indians were better stewards of communities and lands than were the Europeans who settled in North America. Native ways of justice, such as circle sentencing and restorative justice, are making a comeback and are being hailed as credible alternatives to the mostly failed American criminal justice system.

Also, the native populations had a better relationship with the earth than did the conquering settlers. The Western way of exploiting the environment for profit has led to environmental changes that could be responsible for the climate change that has begun to affect millions of Americans. Native Americans, on the other hand, long ago realized that human progress must be coterminous with the natural order, rather than something that is separate or superior to nature. This vision of progress allowed the indigenous people of this hemisphere to live comfortably and in harmony with the earth, which they believed must remain healthy if their people were to survive and thrive.

## Nazi Propaganda

In Chapter Six of *Mein Kampf* (*My Struggle*), Adolf Hitler acknowledges that he views the function of German propaganda as unflinchingly serving the ends of the Nazi Party. Outside Germany's borders, the propaganda campaign in which the Nazis engaged consisted of distributing false information and sowing seeds of distrust among the Allies and between various classes and groups. Within Germany, the Nazis used propaganda in addition to physical force and intimidation to keep the German people in line. The ultimate goal of the internal propaganda campaign was to make Germany appear invincible and present the Nazis as the saviors of the German people.

The ongoing pattern of propaganda often included spreading rumors of secret German weapons that were capable of wiping out entire populations. The propaganda machine even launched a concentrated and successful campaign

to convince British intelligence that the Germans had an entire fleet of He113 Super Fighter planes. The campaign was carried out using false information and photographs of staged settings designed to frighten the British.

Before the German invasion of Austria, Hitler dispatched undercover Nazis to Austria, where they pretended to be Austrian schoolboys. In order to undermine government authority, they staged pranks designed to make the police appear inefficient and foolish. The propaganda continued over the course of the World War II. In France, the Nazis hired professional mourners and palm readers to make it seem as if a German victory against France were inevitable. In order to weaken the bonds among the Allies, the Nazi propaganda machine went so far as to send postcards to French soldiers at the front, informing

them that their wives and sweethearts had run away with British soldiers. The Nazis combed the French gossip columns and traced down any hint of scandal that could potentially give them grounds for blackmailing prominent individuals into supporting Germany. In Belgium, the Nazis engaged in rumor-mongering that allowed them to pit group against group by telling them that King Leopold III was making secret deals with either the Allies or Germany.

Nazi propaganda efforts involved taking control of the German media. One method for maintaining that control was the establishment of the Reich Chamber of Commerce in 1933, and only members of this group were allowed to publish in any medium. Films became a major tool in the plan to spread dissension and distrust. Anti-Semitism was a constant theme in such films. Director Leni Riefenstahl became the voice of Nazi propaganda films, producing such films as the *Triumph of the Will*. The government took over newsreel production within Germany and used newsreels to convince the population that Germany was destined to win the war. Nazi soldiers were sometimes posted at the doors to prevent Germans from leaving theaters without viewing the newsreels.

Many German propaganda films have been lost to history, but one of these films was auctioned on the Internet in 2007. Produced in 1940, *Kampf um Norwegen* depicted the battle between German and Norwegian troops. It is assumed that the Nazis refused to approve its release because of its relatively neutral stance. Political cartoons were also used in propaganda campaigns, and the Jews and the British were popular subjects.

Within Germany, books were seen as a means of exerting control, and strict censorship was enforced. In May 1933, Joseph Goebbels, the minister of public enlightenment and propaganda, instituted a public book-burning at which all material perceived as detrimental to Hitler and the Nazi Party was destroyed.

The radio was also considered an essential tool in spreading Nazi propaganda. To ensure that Hitler was able to spread the word to the people, cheap radios were produced in Germany, which sold for only 35 to 76 marks. Not all of the individuals who broadcasted propaganda were German. One of the most notorious broadcasters was

This 1944 Nazi SS propaganda poster by Nazi propagandist Harald Damsleth promoted Storm SS, a Nazi propaganda tabloid targeted for the occupied Netherlands. The monster symbolizes numerous aspects of American culture that the Nazis found threatening, including race violence, blacks, Jews, Freemasons, commercialism, decadence, jitterbugging, and military violence.

actually born in Brooklyn, New York, but claimed to be a British citizen. That claim ultimately cost him his life. William Joyce, known throughout Europe as Lord Haw Haw because his anti-British propaganda was generally considered ridiculous rather than dangerous, became a fascist in 1933. He used a British passport to move to Germany in September 1940 and subsequently became a German citizen and a staunch Nazi supporter. His claim to British citizenship provided grounds for his conviction of treason, and he was executed on January 3, 1946.

Despite being the chief target of Nazi brutality, European Jews were forced to participate in the propaganda campaign. Prisoners incarcerated at various camps were ordered to send postcards to family members, informing them that were in good health and were being treated well. The most lavish deception involving concentration camps took place in 1944 at Theresienstadt, a Czech camp where Danish Jews were being held. The group included the elderly, disabled war veterans, artists, and musicians. After being forced to accede to requests to allow the International Red Cross to visit the camp, the Nazis put the prisoners to work beautifying the camp. Gardens were planted and buildings were painted. A film, which was never released, was produced that portrayed the inhabitants of Theresienstadt attending concerts and playing sports. After the visit was over, most of the camp's inhabitants were sent to concentration camps such as Auschwitz and Birkenau, where they were killed.

In order to respond to Hitler's campaign of Nazi propaganda, the American government issued the pamphlet *Divide and Conquer* in 1942, explaining the concept of propaganda and what it meant for the American people. The pamphlet cautioned Americans against giving in to Hitler's attempt to eliminate the truth through his tactics of promoting mental confusion, indecisiveness, and panic. In May, the *Saturday Evening Post* broke its own rule against reprinting articles that originated from other sources and reprinted *Divide and Conquer* in its entirety.

The Hoover Institute of Stanford University contains an extensive collection of Nazi propaganda material, including the writings of Hitler, Goebbels, and Alfred Rosenberg, an influential member of the Nazi Party. The Goebbels material

provides a firsthand view of letters he received while serving as head of Hitler's Propaganda Ministry. The collection also includes records on Nazi concentration camps and the International Military Tribunal at Nuremberg, at which war criminals were tried. Another valuable resource for material on Nazi propaganda is the U.S. Holocaust Memorial Museum in Washington, D.C.

## Neurophysiology

Technological developments allow unprecedented observation of brain activity in a continued quest to distinguish truth from lies. Neural monitoring, also called brain mapping, neural mapping, or brain fingerprinting, represents the latest potentially objective attempt in improving the accuracy of determining the truthfulness or veracity of a person's statements. Although the traditional polygraph and neural graphing approaches share common elements, neurophysiological approaches present distinct legal and ethical concerns about how this information might be used in legal courts, law enforcement, and national security.

Historically, observation of individuals' behaviors was the most immediate method of determining their statement veracity. Research on deception detection established connections between several different channels of nonverbal behavior (e.g., touch, hand/foot gestures, facial expressions, eye behavior, scent, posture, use of space, and vocal variation) and different types of deceptive behavior (e.g., highly practiced lies, planned lies, and spontaneous lies). With so many channels to simultaneously attend to, deceivers would often "leak" behaviors associated with the truth, mixed in with controlled behaviors associated with their lie, creating a disparity across the behavioral channels. A weak point within this research was the accuracy levels of humans trying to solely use this information to detect deception.

Deceptive behaviors are frequently associated with physiological changes when anxiety about detection is present. Polygraph administration is designed to heighten this anxiety in participants in order to provide clear responses to questions. A traditional polygraph simultaneously

measured participants' blood pressure, galvanic skin response, pulse, and respiration as indicators of anxiety-induced autonomic arousal. Inherent within this line of deception detection is the erroneous assumption of a universal arousal baseline across all humans. Not all individuals are aroused by telling lies, and even those who would normally be stimulated by this activity may experience lower arousal levels via practice or planning of the lie (i.e., the stimulating effect of any behavior reduces through habituation across practice/performance of the behavior).

Additionally, counter-polygraph training hampers the polygraph's abilities to detect changes in a person's anxiety or arousal by changing their autonomic reactivity, and although steps have been taken to inoculate many of these hampering methods from affecting a polygraph administration, the reliance on external behaviors and internal aspects of an individual's arousal continue to offer weaker evidence. Consequently, courts continue to view polygraph results with suspicion. The most valuable use of polygraph technologies lies in their ability to elicit subject's verbal statements that could subsequently be used in court, even though the actual polygraph test results could not.

### Telling Lies

Where the polygraph focuses on peripheral autonomic activity, brain electrophysiology and neuroimaging focus on direct changes in the brain's activity. Thus, at the core of any neurophysiological approach to deception and lying lies a concern with finding neurophysiological differences between deception and truth. Telling a lie requires an individual to expend additional neural energy beyond what they might expend telling the truth. Additionally, attempting to deceive another requires the deceiver to monitor and produce specific nonverbal behaviors consistent with the false alternate reality of the deception. As such, higher loads of neural energy should be able to be detected. Yet, the more one practices a specific lie, the less energy is required to produce that lie/deceptive attempt.

The blood pressure, pulse rate, respiration, and galvanic skin response, and pupil dilation used in traditional polygraph administration all stem from changes in brain activity, so measuring

the brain directly should, theoretically, provide a more direct, reliable measure of deceptive behaviors. Some of the technologies used in neural monitoring include: functional magnetic resonance imaging (fMRI, a derivative of MRI), using oxygen-consumption and blood flow to map the most active areas of a brain at a specific moment; positron emission tomography (PET scan), which uses radioactive tracers injected into the body to analyze brain tissue by following the flow of the radioactive material; electroencephalography (EEG), which records electrical activity produced by the brain along the scalp; event-related potentials (ERPs), which measure cognitive and sensory experiences using EEG technologies; and “brain fingerprinting,” which is based on unique brain-wave patterns in matching situations (e.g., a familiar scene). Within these technologies, fMRIs only provide images taken each second, whereas EEG and ERP techniques can register activity changes to a thousandth of a second.

Several of these approaches study deception by focusing on matching methodologies, where an individual is shown a familiar/unfamiliar scene, and then is asked whether they recognize the scene or not. Similarly, participants are sometimes asked to say “true” or “false” in response to reading statements, creating either true or false statements in the process. These methods were well established in the 1980s, using event-related potentials (ERPs), and have continued to be utilized with more sophisticated technology (e.g., fMRIs, PET scans, and even more sensitive EEG technologies). All of these approaches suffer from external and ecological validity challenges, attempting to generalize findings of their samples to other deceptive encounters, as well as poorly resembling actual deceptive events and activity. What is emerging within this research line is a focus on deceptive constructions and decisions to deceive, both of which offer promise to better inform those seeking to understand neural aspects of actual human deception. A practiced lie is likely to take less neurological energy than a planned one, and a planned lie is likely to take less energy than a spontaneous one. Although this finding is well established within the cognitive research platform, it is only now beginning to emerge as a viable research question to pursue within the neural monitoring area.

Although historically some critics have suggested that specific brain areas need to be consistently associated with deceptive behaviors before neural monitoring can be accepted as a viable deception detection technique, more recent neurophysiological research shows progress toward this very goal. In regard to neuroscience as a form of lie detection, specific regions of the brain have been analyzed in order to uncover patterns of truth-telling, deception, and false memory. Lies can show increased activity in the entire prefrontal cortex. Within this, the anterior cingulate cortex seems to play a role because of the conflicting information between truth and the deceptive reality that is constructed, though rehearsed and/or practiced lies do not seem to involve the area as much as spontaneous ones.

The general capacity to deceive rests within the neocortex, the most recent part of the human brain to evolve. This is the outer layer of brain tissue comprising a majority of the overall brain volume. Correlations exist between the larger size of a primate’s neocortex and efficacy at deceiving their primate associates. Lies show increased activation of the inferolateral cortex, along with higher activation levels within the left middle temporal areas, right anterior cingulate, right inferior front, right middle frontal, and right orbitofrontal areas. The dorsolateral prefrontal cortex activates when individuals pretend to know information that they do not know, as opposed to telling the truth. Conversely, the right anterior hippocampus activates when individuals present false recognition, as opposed to lying or telling the truth.

Beyond the matching and constructive areas of deception lies an area investigating the inhibition of honest responses in favor of deceptive ones. Similar to lie constructions, these activities require greater amounts of human energy to produce. In this case, it is because the individual must withhold the true state of things while simultaneously creating a plausible, but alternate reality and communicate that reality convincingly. Inhibitions of honest responses, while producing deceptive ones, produce fairly reliable ERP responses within the medial frontal areas, though these areas are focal points for multiple sensory modalities and play a role in a host of executive decision-making tasks of the brain.

A caveat in terms of this research area's external validity is that the vast majority of published neural monitoring research into deceptive behaviors used cooperative individuals, bearing little resemblance to actual deceptive interactions.

### **Market Aspects of Neural Technology and Deception Detection**

The events of 9/11, and the resulting dramatic increase in all things pertaining to national security, have pushed forward the importance of developing more reliable and objective methods of interpreting statement veracity. Research funding and markets for neural monitoring technologies have also dramatically increased. Companies such as Brain Fingerprinting Laboratories, No Lie MRI, and Cephos Corp. offer neural-based lie-detection services, advertising to lawyers, prosecutors, and other firms such as the CIA and FBI, in attempts to provide 21st-century versions of the traditional polygraph.

The U.S. military has become increasingly interested in the neurophysiological possibilities of deception detection. In antiterrorism situations, brain imaging may help distinguish enemy combatants from those who pose no risk. Though the Federal Employee Polygraph Protection Act of 1988 prohibits employees from having to undergo lie-detector examinations, the federal government is one of the highest polygraph users for security clearances and other purposes.

### **Legal Concerns**

Many legal systems rely on witness testimony, and have developed checks to determine the veracity of these witnesses' statements. Historically, taking an oath on a bible would create enough fear to confidently make most individuals tell the truth. Added to this was the ability of cross-examinations to ferret out misstatements or lies. Finally, the court could find a liar guilty of perjury, and subject the deceptive individual to incarceration. Yet, in this process, juries and judges introduce subjective elements in judging false or true statements, creating inconsistencies/inaccuracies from case to case by taking into consideration ethnic and other social information, whereas neural monitoring machines would be more objective by using pre-established algorithms and activity thresholds to establish statement veracity.

Two major legal concerns currently associated with neural monitoring in the United States pertain to the Fourth and Fifth Amendments. Neural issues regarding the Fifth Amendment apply, where individuals' brains should not make self-incriminating information available to others. Beyond this concern lies issues pertaining to the Fourth Amendment, dealing with privacy and unlawful search and seizure of an individual's personal property; in this case, his or her thoughts. Unlawful invasion of a person's brain thus becomes an issue and is frequently debated within neurolaw discussions.

The *Miranda* case ruling prevents data collection from unsuspecting individuals, where that data could ultimately be used against them as evidence. At present, obtrusive data collection methods (e.g., lying inside an MRI scanner or wearing an EEG hood or cap) prevent such an unconscious collection situation. Yet, future development of unobtrusive remote data collection technology seems realistic because this would allow greater equipment portability to field situations where combatants are interrogated and the veracity of their statements could have large-scale safety implications.

### **Concerns Regarding the Neurophysiology of Lying and Deception**

Unlike polygraph machines, current neural monitors tend to focus exclusively on the brain area of the nervous system. Some have voiced concerns regarding these machines' abilities to read a person's thoughts in an Orwellian style of "big brother" government agencies able to tell whether a person's statements are truthful or not.

These concerns attribute greater capabilities to neural monitoring technology than currently exists, though this line of technological development elicits concern regarding how pervasively this technology will be used, by whom, against whom, and for what purpose. There is concern regarding mental surveillance versus neural monitoring. Yet, the line of development is heading in the direction of the ability to accurately and precisely determine the veracity of a person's statements.

## New York Sun's Moon Series

The *New York Sun's* Moon Series refers to a series of six articles published in the *New York Sun* newspaper in 1835 that claimed to describe life on the moon. The articles are believed to have been written by Richard Adams Locke (1800–71), the editor of the *Sun*, and helped insure the success of the newspaper and the "penny press." The Moon Series is still regarded as one of the great media hoaxes of all time.

The *New York Sun* began publication on September 3, 1833, and was the first penny press newspaper in the United States. The paper's founder was Benjamin H. Day (1810–89). Penny press newspapers were intended to appeal to a larger audience and relied on street sales and advertising for their revenues. The penny press challenged the so-called 6¢ newspapers, which had small circulations and relied on funding from political parties or subscriptions.

Day, the *Sun's* publisher, was responsible for publishing the stories about the moon, the first of

which was printed on August 26, 1835. The story appeared under the headline, "Great Astronomical Discoveries Lately Made By Sir John Herschel, L. L. D. F. R. S. & c. At the Cape of Good Hope [From Supplement to the *Edinburgh Journal of Science*]." The hoax had actually begun a few days earlier. In the Friday, August 21, 1835, edition, a notice appeared on page two, announcing that "We have just learnt from an eminent publisher in this city [Edinburgh] that Sir John Herschel, at the Cape of Good Hope, has made some astronomical discoveries of the most wonderful description, by means of an immense telescope of an entirely new principle." The articles would begin appearing the next week. The journal that the *Sun* said the articles would be reprinted from had actually ceased publication in 1833.

The stories were supposedly written by a Dr. Andrew Grant, who claimed to be the traveling companion of Sir John Herschel (1792–1871) and a pupil of his father, Sir William Herschel (1738–1822), the discoverer of Uranus. John Herschel, the leading astronomer of the day, was identified by Grant to be the source of the discoveries in the articles. Grant, the author, was fictitious. The series of six articles, published in the next six issues of the paper, claimed that there was life on the moon—including unicorns, bison, goats, beavers that walked upright on their hind legs, and four-foot-tall flying man-bats (which Grant called *Vespertilio-homo*) that built temples. There were also trees, oceans, and beaches.

### The Six Articles

The August 25 edition carried the first story, which described the new telescope. This telescope was so powerful that it could be used to view distant objects with such magnification that it was possible to study "even the entomology of the moon, in case she contained insects upon her surface." It was a large telescope, measuring 24 feet in diameter, and it had two lenses. The second lens, which the article called a "hydro-oxygen microscope," projected an image onto a screen. This made the image large enough to see even the smallest objects.

On August 26, 1835, an article on plant and animal life on the moon was published. According to the article, Herschel first examined the moon through the telescope on January 10, 1835,

seeing “a beautifully distinct, and even vivid representation of basaltic rock.” Grant wrote that these rocks were covered by red flowers. In addition to the plants, Grant wrote that Herschel had discovered animal life on the moon. There were herds of animals that appeared to be similar to bison, goats, and “a strange amphibious creature, of a spherical form, which rolled with great velocity across the pebbly beach.”

The article that appeared on August 27, 1835, started by describing some geological features on the moon, including the existence of oval-shaped mountains and extinct volcanoes. Grant presents a list of the plants and animal life that Herschel had discovered on the moon: 38 species of trees, twice this number of plants, nine species of mammals, and five of ovipara. This piece focused on the biped beaver. These animals walked on their hind legs and built and lived in huts that were, according to Grant, “constructed better and higher than those of many tribes of human savages.” Grant thought that signs of the intelligence of these animals were the puffs of smoke that were seen coming from the tents. This had led Herschel to believe that these beavers had learned how to use fire.

On Friday, August 28, 1835, an article reported the existence of four-foot-tall flying man-bats (which Herschel supposedly called *Vespertilio-homo*). The man-bats were “covered, except on the face, with short and glossy copper-colored hair, and had wings composed of a thin membrane, without hair, lying snugly upon their backs.” Their faces, “a yellowish flesh color, was a slight improvement upon that of the large orang outang.” Grant wrote that confirmation of the existence of the man-bats would be forthcoming from ministers who had been allowed to visit the observatory and view the man-bats.

The Saturday edition, published August 29, 1835, described the discovery of what appeared to be a temple, built of polished sapphire, with a roof made of yellow metal that looked like flames moving toward the sky. The astronomers speculated as to the meaning of this design, but decided in the end that they would avoid “indulging in speculative theories, however seductive to the imagination.”

The paper did not publish on Sundays, so the sixth and final article in the series appeared on

Monday, August 31. In this article, the author reports that astronomers discovered a superior order of *Vespertilio-homo* living near the temple. These man-bats were “of a larger stature than the former specimens, less dark in color, and in every respect an improved variety of the race.” Grant then reported that the observations had ended because they had accidentally left the telescope in a position where the sun’s rays had caused the lens of the telescope to act as a “burning glass,” setting fire to the observatory. By the time they had completed the repairs to the observatory, the moon was out of their sight.

Grant ended his story by writing that they did resume their observations of the moon the next month, when he found yet another group of *Vespertilio-homo* who “were of infinitely greater beauty, and appeared in our eyes scarcely less lovely than the general representations of angels by the more imaginative schools of painters.” Grant wrote that more would be reported in “Dr. Herschel’s authenticated natural history of this planet” which would soon be published.

### Reaction to Series

The articles created a sensation. The stories were reprinted in newspapers in the West and in Europe. The *Sun* published a special-edition pamphlet that included all six articles, which it sold for one shilling. The newspaper also sold prints showing Herschel’s discoveries, including the lunar animals and the Ruby Coliseum, which appeared to be an amphitheater where the man-bats were seen.

On September 1, the *Sun* printed a story responding to some of the comments about the articles. The story said that those newspapers that were critical of the stories proved that, “Consummate ignorance is always incredulous to the higher order of scientific discoveries, because it cannot possibly comprehend them.”

For the most part, the skeptical newspapers and readers did not really condemn the *Sun*. In his 2009 doctoral dissertation, Mario Castagnaro explained the following:

The early 19th-century was a culture of curiosity, one in which readers did not have clear-cut expectations about truth and fiction and the two usually blended together on

newspaper pages; credibility was not the chief reason people picked up newspapers.

One newspaper that was critical of the *Sun*'s stories was James Gordon Bennett's *New York Herald*. In a column that appeared in the *Herald*'s August 31, 1835 edition, Bennett wrote that "the town has been agape two or three days at the very ingenious astronomical hoax." Bennett wrote that the *Sun* had claimed that the articles had been originally published in the *Edinburgh Journal of Science*. However, Bennett observed there was "no work of that kind being now published. A few years ago there was such a work, but it merged into another journal published in London."

On September 3, 1835, Bennett's *Herald* again attacked the *Sun* for its hoax:

We mean now to show up the *Sun*—the impudent *Sun*—the unprincipled *Sun*—the mercenary *Sun*—the low bred *Sun*—the *Sun* that hoaxes the public—that tells untruths for money—that makes fools of the wine [sic]—that cheats the whole city and country. The revulsion of public sentiment, is fast accumulating. Its astronomical hoax will touch the *Sun* yet to the quick.

Bennett continued the attack the following day, writing that the *Sun*'s stories were "highly improper, wicked, and in fact a species of impudent swindling."

The *Sun* would defend itself against the *Herald* and other skeptics, asserting that if the articles were a hoax, then the paper itself was a victim because it was reprinting what had first appeared in Europe. In its September 16, 1835 edition, the paper replied to its critics that, "Certain correspondents have been urging us to come out and confess the whole to be a hoax; but this we can by no means do, until we have the testimony of the English or Scotch papers to corroborate such a declaration." Of course, the articles were a hoax. Herschel, who was working in South Africa during this time, did not observe the moon. Herschel wasn't even aware of the *Sun* articles until much later when he was given copies of the newspapers. His initial response was bemusement: "It is too bad my real discoveries here won't be that exciting." However, in an 1837 letter he would

A portrait of a man-bat, which the fictitious New York *Sun* writer Dr. Andrew Grant called "Vespertilio-homo," appears in the August 31, 1835, edition of the newspaper. The paper claimed that because the story was originally published in a scientific journal, it was the victim of the hoax, not its readers.

complain about the questions he received from people who believed the stories were real: "I have been pestered from all quarters with that ridiculous hoax about the Moon—in English, French, Italian, and German!"

Another person who was annoyed by the *Sun* hoax was Edgar Allen Poe (1809–49), who was convinced that the *Sun* had gotten the idea for the stories from an article he had published in the *Southern Literary Messenger* a few months earlier. In his hoax, "Hans Phaall—A Tale," a man had sailed a balloon to the moon. However, few had read Poe's story, and the *Sun* stories attracted international attention.

There have been questions about Day's motivation in publishing the moon hoax articles. Obviously, increasing circulation of the newspaper was a goal. Day's paper relied on newsboys to sell the paper on New York's streets, and the moon stories certainly attracted curiosity and readers, selling

more papers. In a letter written by Locke in the May 16, 1840, edition of the *New World* newspaper, the now former editor of the *Sun* explained his intent had been to satirize what he called the “theological and devotional encroachments upon the legitimate province of science.”

The *Sun*’s Moon Hoax was the first time that the mass media demonstrated its power to shape popular attitudes and spread information. This would become a greater concern to many in the years to come.

## News Media: Internet

Historically, information on current events was transmitted by word-of-mouth. News was transmitted by couriers and official government bulletins. As communication and trade grew prior to the Industrial Revolution, information was transmitted in official and private handwritten sheets. Official sheets in Venice in the 1500s cost one *gazetta*. With the rise of newspapers in the 17th century, some kept the name “gazette.”

The rise of print media as broadsheets, and then as morning and evening papers, was in part an

outgrowth of the Industrial Revolution. Lloyd’s of London and other insurers needed news in order to keep up with shipping departures and arrivals, as well as losses. Commercial interests needed market information to determine market prices that were affected by wars, famines, droughts, plagues, and other adversities.

News gathering reporters eventually traveled in order to report on the progress of military campaigns or other events. Dispatches from battlefronts became stories printed (eventually with pictures) in city and town newspapers.

After World War II, news issued in printed media was brought or sent to the newsroom by reporters or by reporters in the field through wire services. There, it was edited, set in type, and printed on cheap newsprint. Print media moguls like William Randolph Hurst exercised great power through their organizations’ printed words. Newspapers, however, began to face competition from broadcast media. As radios and then televisions increased from just automobiles and large sets in homes to portable transistor sets, broadcast media began to exercise more power. Newspaper readership sales and advertising revenues began to decline.

By the 1980s, cable systems began to bring large numbers of television programs into homes via cables. This was eventually followed by commercial cable news systems. The most important cable news channel was established by Ted Turner in Atlanta, Georgia, the Cable News Network (CNN). The rise of television programming lasting 24 hours a day, seven days a week, made “breaking news” standard operating procedure.

### Objectivity

Readers and television viewers expect objectivity in news reporting. Many readers expect stories to be written and edited as factual information, not biased treatments. This is a change from the early history of newspapers, when they were often the communication organs of political parties. Some newspapers, such as the *Arkansas Democrat Gazette*, have retained their earlier partisan names. In reality, most newspapers are not objective but have an editorial position that is liberal to moderate or moderate to conservative. Stories are printed that are newsworthy. Editors decide what is and what is not “news.” A story is newsworthy if it is relevant to the public or to a

special audience. Biased editorial selectivity leads to biased news reporting and interpretations.

These biased print media sources, including news magazines such as *Time* and *Newsweek*, began to face competition as politically and ideologically disgruntled readers and viewers turned to talk radio for news and opinions. Cable news programming also faced this politically driven competition from talk radio and then from Internet news media.

Advances in computers and Internet connections that created the World Wide Web allowed for the growth of global connections. News media, both print and cable, had new competition.

Internet news media rapidly grew after 2000. The Internet provided instant access to news on a global basis. It also allowed for real-time exposure to ongoing stories. Opportunities for instant feedback or for forms of participation rapidly grew. Via the Internet, consumers could access news stories anywhere in the world, anytime.

The Internet created a much more democratic and egalitarian opportunity for people to create news sources and interpretations that could appeal to people of shared beliefs. Many people began to practice online journalism. Private individuals began to report, produce, and distribute news via the Internet. Advertising soon followed, and so did misinformation and lies.

Internet news opportunities have attracted bloggers and others who report news. One successful site is the Drudge Report, a news aggregation Web site run by Matt Drudge and others. With more and more people moving from print media to electronic media via their personal computers, telephones connected to the Internet, and Internet devices such as the Apple iPad, commercial print media have also moved online.

### Misinformation

Bloggers and others are able to detect mistakes and frauds committed by the mainstream media, even when online. A major case arose when aging reporter and CBS mainstay Daniel Rather reported on *60 Minutes Wednesday* (September 8, 2004) that President George W. Bush's service records from the Texas Air National Guard had been found. The claim was made that the records had been found in the personal files of Lieutenant Colonel Jerry B. Killian. The records alleged that

while in the Texas Air National Guard, then Lieutenant Bush had served with less than distinction. However, when posted online, bloggers quickly denounced the records as forgeries. The first report was posted on the Free Republic, which is an Internet forum for activists, many of whom describe themselves as conservatives. They post anonymously but are known as Freepers using screen names. They quickly demonstrated that the type fonts used to write the documents did not exist in military typewriters at the time that President Bush was serving. CBS and Daniel Rather were later involved in legal actions because of the "Rathergate" incident.

Another Internet news media source is the Onion. Some of the stories are funny spoofs that will only fool the very uninformed. However, to some people, this and similar sources can spread disinformation. BigGovernment.com, BigHollywood.com, the late Andrew Breitbart's conservative news site Breitbart.com, and Arianna Huffington's liberal Huffington Post are more responsible Internet news providers. Some political sites on the left have attacked adherents of other viewpoints with baseless, vicious stories.

There have been many famous people who have been victimized by misinformation, or by lies posted on the Internet. In some cases, the lies were hoaxes or pictures that were manipulated to create a false image. Morgan Freeman and other Hollywood celebrities have been falsely reported to have died in online celebrity hoaxes.

One very dramatic hoax involved Notre Dame's football player, Manti Te'o. He was informed that his online girlfriend, Lennay Marie Kekua, had died of leukemia about the time he also lost his grandmother. He then inspired his teammates to win a game for them. It was eventually revealed that Lennay Kekua was a fabrication, a hoax masterminded by Te'o's friend Ronaiah Tuiasosopo.

The 2013 Boston Marathon terrorist attack evoked an outpouring of citizen journalism. It was accompanied by charity scams and by reporting of rumors and false information about who the killers were. The Reddit newsfeed carried photos of possible suspects, who it was later discovered were falsely identified. Some critics of citizen journalism believe that the lack of editorial guiding hands contributes to false rumors plaguing Internet media.

Some well-known journalists and commentators have been accused of using weak or conflicted sources in order to push an agenda via the Internet. While not exactly falsehoods, the weak evidence supporting stories such as dramatic climate change or the reverse position misleads people.

In 2013, Edward Snowden released information about secret Internet spying conducted by the U.S. government. His whistleblowing attracted global attention. He soon became the target of numerous false stories on many Internet news sites.

### Censorship

The Internet has provided forums for radicals on both the left and right where they can share their views. Some of these groups are anarchists, communists, neo-Nazis, or environmental extremists. On these sites are stories that may exaggerate subjects such as climate change and/or make unsubstantiated claims. Their Internet information media sites allow for publications that would be censored or barred in more mainstream media.

In some countries, such as Singapore, there are restrictions on sites that simply report on conditions in the country. What is “objectionable” to the government is a classic censorship issue. In the case of Singapore, mere criticism of the government or of other aspects of Singapore, even if true, is “objectionable.” Singapore’s government policy is that nation building is more important than accurate news reporting, even online journalism.

Some Internet news media are private or secretive. If pressure is applied to Internet providers such as Yahoo! to block these unwelcome sites, they are likely to go underground. The response from some of the more radical groups would likely be to engage in cyberattacks or to become more covert and hostile.

By 2013, most American voters had abandoned print news media for television and the Internet. Only half of voters polled believed that traditional news media, even online, was trustworthy.

## News Media: Print

In journalism, honest reporting is a fundamental value. Despite this ethic, deception has a long history in journalism that dates as far back as the 19th century. The definition of deception in journalism has been debated by those inside and outside the industry. According to Deni Elliott, a prominent researcher on deception, journalists are deceptive if they “have, in the course of an investigation, through intentional act or assertion, attempted to initiate or sustain a false belief, or if they have allowed another person, with whom they have a special relationship, to initiate or sustain a false belief.”

However, some journalists have argued that the second half of this definition, allowing someone to form the wrong impression, is not deception, but rather pretense. A term coined by journalist James Reston, “pretense” is a passive act, whereas deception is an intentional act. Regardless, intentional deception in journalism can be achieved in

two ways: investigative deception and informative deception.

### Investigative Deception and Informative Deception

Investigative deception is to deceive by false identification with the purpose of gathering information. This means that the reporter falsely identifies him or herself and his or her intentions while exploring a story. A popular term for this kind of falsification is “sting story,” deriving from the traditional law enforcement term “sting” that is used to describe deceptive operations used to catch illegal activity, of which there exist many examples.

In 1887, American female journalist Nellie Bly successfully feigned insanity to gain entrance into the Women’s Lunatic Asylum on Blackwell’s Island and examine the living conditions of patients. Because she falsely identified herself as mentally ill in order to obtain information on how the asylum was operated, she engaged in investigative deception. Her subsequent published report launched an investigation by a grand jury into the asylum’s operations.

Another famous instance of investigative deception occurred in 1979, when *Chicago Sun-Times* reporters Pamela Zekman and Zay Smith pretended to be the owners of a new bar they named The Mirage. In their undercover operation, they found that city inspectors of the recently opened bar offered to accept bribes so that Zekman and Smith wouldn’t have to carry out costly repairs mandated by the state. Several inspectors were indicted after the newspaper’s four-week exposé of the corruption.

In 2005, after the *Spokesman-Review* in Spokane, Washington, learned that the city’s mayor, James West, was participating in conversations in a gay Internet chat room under an assumed name, the newspaper hired a forensic computer expert, who created a false, gay persona he used to chat with West. As a result of this sting operation, the newspaper reported that West had used the chat room to help someone he thought was an 18-year-old high school student receive gifts, favors, and a City Hall internship. The story revealed that West, a Republican with an antigay political agenda, was gay himself, and resulted in his recall from office.

Informative deception occurs when journalists either present fabricated or altered information,

or selectively exclude certain pieces of information in their writing. There are many examples of this type of deception. *Washington Post* reporter Janet Cooke authored a story called “Jimmy’s World” in 1980 that detailed the life of an 8-year-old heroin addict, which moved many of the *Post*’s readers and caused the mayor of Washington, D.C., to authorize a thorough police search for the boy. Cooke later confessed that “Jimmy” never existed and that she had completely fabricated the story.

In 2003, up-and-coming *New York Times* reporter Jayson Blair falsified and plagiarized information in at least 36 of his articles, many of which covered high-profile incidents. He published

Nellie Bly (the pen name of Elizabeth Cochrane) in 1890, in her famous checkered traveling suit. As a crusading young reporter, Bly once faked insanity to gain admittance to a lunatic asylum, from which she gathered information for a scathing exposé.

five articles on the homecoming of prisoner-of-war Jessica Lynch in 2003 that contained blatant falsehoods, including interviews with family members, when in fact he never spoke to anyone in her family. In 2004, FOX News retracted an entirely false report by political reporter Carl Cameron that claimed that presidential candidate John Kerry, who had gotten a manicure before a debate, had said: “Women should like me! I do manicures.”

### Consequences and Reasons for Deception

The consequences of engaging in either investigative or informative deception can be severe given the ethic of honesty and truthfulness in journalism. When the *Chicago Sun-Times* published its report on The Mirage, investigative reporters praised Zekman and Smith for their work. However, the two journalists did not receive a Pulitzer Prize because of their use of dishonest methods to procure their information. Benjamin Bradlee, the executive editor of the *Washington Post* from 1965 to 1991 who also sat on the review board of the Pulitzer Prize committee, at the time said, “How can newspapers fight for honesty and integrity when they themselves are less than honest in getting a story?”

Exposure of informative deception often results in resignation. For example, Cooke resigned from the *Washington Post* after “Jimmy’s World” was revealed to be fabricated, and she returned the Pulitzer Prize she had won just two days before she confessed. Stephen Glass, a rising star in journalism, partially fabricated 27 of the 41 stories he wrote for *The New Republic*, and he was fired when his trail of deceit was discovered in May 1998. Blair resigned from the *New York Times* when his history of plagiarism and fabrication was discovered. The *Times* called the incident “a low point in the 152-year history of the newspaper.”

Why do journalists deceive? In both kinds of deceptive journalism, there are typically professional motives: to report compelling stories that will capture attention, improve the author’s reputation, and ultimately drive the newspaper’s revenue. By engaging in informative deception, many journalists succumb to the pressures of promoting their careers. For example, in explaining why he fabricated as much as he did, Blair said he was living up to the expectations of those around him.

Some journalists who have engaged in investigative deception, however, have further justified their

actions with selfless reasons. An example of this occurred in 1977, when five *Milwaukee Journal* reporters posed as patients and visited local doctors. They discovered that a number of the doctors they saw gave them whatever drugs they asked for. These doctors were consequently investigated by the State Medical Examining Board after the *Milwaukee Journal* reported this information. Thus, this act of deception functioned to benefit the larger community, because the undercover operation exposed doctors who were not serving their patients appropriately, and it eventually ensured that these doctors would be held accountable.

The question of whether investigative journalism deception can be justified is frequently examined. One view is that journalists should not be exempt from the social norm of honesty to which all citizens adhere and upon which journalism prides itself. Another view is that deception is justified if it uncovers serious threats to society. After former *Los Angeles Times* writer Kevin Silverstein drew fire for his own undercover reporting in 2007, in which he posed as a representative of a London-based energy company to lobbyists, he described how there was too much emphasis on the fact that he lied and not enough emphasis on the fact he had exposed serious corruption in the Washington, D.C., area.

There are two types of journalism deception: investigative and informative. Examples of both are plentiful; however, investigative journalism deception has been on the decline in recent years. This is because investigative journalism as a practice has waned significantly since the emergence of the Internet, which has stunted the growth of traditional journalism. Roberta Baskin, director of the investigative reporting team at WJLA, a television station in Washington, D.C., states that “traditional news rooms [have] cut their budgets and the first thing that they want to cut out is investigative reporting because it can be litigious, it takes a long time to gather your information [and it] takes more resources.” While some people believe that deception for the sake of uncovering serious dangers is justified, informative journalism deception is generally frowned upon.

## News Media: Television and Radio

Individuals' understanding of the role of the news media, specifically television and radio news, in deceiving the public comes from what they know about how a journalist may present or omit certain information. Individuals must consider if the news reports on television or the radio are in fact accurate. Mass communication scholars and criminologists have been examining this for some time, as the media impacts how various news reports, and specifically crime news, are received and processed. If these reports are inaccurate, the

public receives an inaccurate account of news in their area, the country, or the world. The credibility of sources and of a specific medium must also be considered in examining broadcast news accuracy. The over-representation of crime stories and the use of video news releases are deemed to be major forms of exaggerated or fake news, which can mislead the public.

Much of what is understood in terms of journalistic deception comes not just from news-gathering practices, but also from the types of relationships journalists have with their target audiences. Additionally, the stories that are omitted must be considered as well as the stories that are covered. Deception has been documented to occur in at least one-quarter of all conversations, and media outlets such as radio and television stations would not be immune to deception when presenting the news. In fact, journalistic deception, can be defined as the act of communicating messages verbally (that is, telling a lie) or nonverbally (that is, withholding of information). Both of these forms of deception have been shown to be routine in broadcast news, with the goal of initiating or maintaining a false belief with the radio listeners and television viewers.

### Role of Broadcast Media in Deception

The role of the media in lying and deception is understood through the types of stories they are pressured to present. This is something that television, radio, newsprint, and the Internet all fall victim to. Specifically, television and radio news must have attention-grabbing stories to draw viewers and listeners.

However, a key question must be asked: Are such news reports accurate? The creation of television and radio news, the presentation of these stories, and the accuracy of these news accounts have been considered by mass communication scholars for several decades. Criminologists also have considered the reporting of crime news for decades, as crime is often deemed newsworthy and open to manipulation by news agencies such as television and radio stations. For example, crime stories will vary based on the medium on which they are broadcast (that is, radio or television), and where in the country they are broadcast: larger urban areas may be more selective about which murders or violent acts are reported

because of the frequency of these crimes and the space limitations of their broadcast news programs, while smaller, suburban areas are more likely to report on all violent acts, as they are less frequent.

### Standards of News Credibility

When considering deception in radio and television news, it is important to examine the perceptions the public has concerning the credibility of these broadcast media. Research in the field of mass communications examines the perceived credibility that citizens attribute to media sources, such as radio and television news. Credibility can be defined as the level of trustworthiness and expertise attributed to the news media. News reports are supposed to be truthful and unbiased, not deceptive. If individuals perceive radio or television news to be credible, they will grow to rely on these outlets for news, thus increasing their daily exposure to news.

The field of communications has identified two forms of credibility that are important to consider. The first is source credibility, which focuses on the perceived truthfulness of individuals communicating in the medium (that is, radio or television). Key components to source credibility include, but are not limited to, safety, qualifications, dynamism, competency, and objectivity. A second form of credibility is medium credibility. With medium credibility, people judge the specific medium (that is, radio or television) itself, and not the source presenting it.

### Crime News and Deception

Various constituencies use the media (as much as their power will allow) as an outlet to have their concerns publicly aired. In fact, it has been proposed that the more exposed an audience is to a particular issue through television and radio, the more concerned they will be about it. To use crime stories as an example, it has been argued that news consumers are indeed saturated with crime-focused stories. Research indicates that most television stations begin the evening news with a crime story, close to one-third of news stories concern crime, and crime news is included in news broadcasts almost twice as much as political news. In recent years, researchers have argued that crime has ceased to be reported solely for

informative purposes, and its presentation is more for entertainment. However, this presentation is clearly deceptive to the audience.

### Video News Releases

A video news release (VNR) is the ultimate form of lying and deception in television news. A VNR is a news segment that appears to be produced by television journalists, using a tone and format similar to that of television news. However, VNRs are created by public relations agencies, advertising firms, government agencies, and other organizations and individuals as a means of obtaining television coverage that will advance their particular cause, product, or interest. These prepackaged “news segments” are then broadcast during a television station’s news programming.

Many stations air prepackaged VNRs in their entirety, without adding footage or other journalistic commentary. Some large media conglomerates, such as Clear Channel, News Corp./FOX Television, Viacom/CBS, Tribune Co., and Sinclair Broadcast Group, produce their own VNRs. Although other news media have come to the forefront in recent years (for example, Internet news), many citizens still receive their news by watching television. That is why it is imperative to understand how and why VNRs are used.

The use of VNRs is widespread; over half of the U.S. population has been exposed to them. VNRs can be syndicated, which broadens the reach of these messages. Additionally, VNRs are aired in markets of all sizes, as stations will use VNRs to reduce the costs of filming, producing, and editing their own news reports, while masking VNRs as their own unique reporting. In some cases, a station anchorperson may revoice the narration before the VNR is aired.

## Nietzsche, Friedrich

A concern with lies and deception is central to the oeuvre of German philosopher, philologist, and cultural critic Friedrich Nietzsche (1844–1900). In his 1873 essay “On Truth and Lies in an Extra-Moral Sense,” Nietzsche argues that language operates on the basis of a social contract that obligates everyone to lie according to fixed linguistic convention. He claims that language has no interest in the objective truth of what he calls, following Immanuel Kant, the “things in themselves.” Instead, language only designates the subjective relations between humans and the world around them through metaphors that correspond in no way to the essence of external objects. For the purpose of security and consistency, society obligates individuals to use a fixed set of metaphors, and by the force of habit, individuals forget that the words and concepts that they consider truthful are nothing but metaphorical functions of their conventional morality.

Significantly, Nietzsche’s argument itself relies heavily on metaphors, many of which revolve

around the opposition between life and death. For instance, he compares language to a Roman columbarium and calls it a graveyard of perceptions, suggesting that the lies that society obligates individuals to use to designate things kill their colorful and vivid first impressions and intuitions. Nietzsche’s own heavy use of metaphors seems necessary because he believes that a criterion for “correct perception” is not available: between the human subject and the perceptual object there can only be an aesthetic relation at best.

Therefore, Nietzsche concludes the essay by distinguishing between “rational” and “intuitive” people, who use metaphors in different ways. Whereas rational people cling to an immense “framework and planking of concepts” and live regular and prudent lives in scientific disenchantment, intuitive people, such as the ancient Greeks, dare to choose beauty over need and embrace the “immediacy of deception,” which can lead to the establishment of art and culture. Like various other 18th- and 19th-century German critics of modernity, Nietzsche, who was a professor of classical philology in Basel, Switzerland, from 1869 to 1879, often presented an idolized view of ancient Greek culture in order to critique what he saw as the lifeless and artless utilitarianism of modernity.

Critics have argued that what Nietzsche discovers in “On Truth and Lies in an Extra-Moral Sense” is not that language as such is a lie but the inadequacy of so-called correspondence theories of truth, which hold that a linguistic utterance is true only if it corresponds to a fact in the world. According to this objection, Nietzsche’s discovery of language’s failure to correspond to “things in themselves” should simply lead him to adopt either a coherence theory of truth, which holds that the truth of linguistic utterances is determined by their coherence with other utterances; or a pragmatic theory of truth, which views those linguistic utterances as true that successfully organize individuals’ experience of the world for practical purposes. However, this objection fails to engage with Nietzsche’s philosophical project as it develops in his mature work, which might be summarized as a radical critique of lies and deception in the present, composing a “prelude to a philosophy of the future” (this is also the subtitle of his 1886 book *Beyond Good and Evil*).

Nietzsche's fundamental orientation toward the future first manifests itself in *Human, All Too Human: A Book for Free Spirits* (1878), in which he calls for "historical philosophizing." In *Human, All Too Human*, Nietzsche argues that all previous philosophers have mistakenly taken their contemporaries as the measure of all things, attributing an eternal essence to a notion of humanity that has in fact been constituted historically by particular religions and particular political events. Just as Charles Darwin argued in *On the Origin of Species* (1859) that species do not have a transhistorical essence but evolve over time, Nietzsche maintains that there are no eternal facts or absolute truths and that everything, including humanity itself, is in a constant process of becoming. This fundamental insight harbors the possibility of progress as originality, because if people disentangle themselves from their false, essentialist, humanist metaphysics, they might create a better culture and a better morality. They might do this by comparing existing world views, customs, and cultures and by making conscious decisions, relying on their now liberated aesthetic sense, about which values are best.

### Scientist or Allegorist?

Given Nietzsche's consistent project of exposing lies and deception, it might seem surprising that although he often presents himself as a scientist (compare his book *The Gay Science*, 1882), most of his books are not systematic treatises but collections of aphorisms, and he relies heavily on fiction to develop his arguments. In what is perhaps the most famous instance of Nietzsche's historical philosophizing, *On the Genealogy of Morality* (1887), he argues that individuals have forgotten that their current values do not reflect eternal moral truths but result from historical struggles for hegemony of certain value systems over others. More specifically, he seeks to demonstrate that Christian morality is a cynical lie.

Nietzsche develops his argument through the following allegory. Once upon a time, the word *good* reflected an aristocratic value judgment based in a feeling of superiority. The noble and mighty defined themselves and their actions as "good" and called those they considered low, base, and plebeian "bad." However, a slaves' revolt in morality took place in which the dominated

classes managed to radically reverse the values of their aristocratic masters, calling their former masters not "bad" but "evil," out of *ressentiment* (resentment), and designating themselves as "good" by comparison.

This radical reversal of values led to the establishment of a reactionary morality that was not grounded in affirmation but in negation. Contrary to the "naturally" felt, active happiness of the former masters, the former slaves lied themselves into an artificial, passive happiness by telling themselves, through "sublime self-deception," that they were not evil and therefore good. This myth allegorizes the triumph of Jewish and Christian morality over the "life-affirming" values of the Romans and other "noble races." Nietzsche, whose father and grandfather were Protestant pastors, denounced Christianity as a nihilistic ideology premised on a hatred of reality (compare also *The Anti-Christ*, which he wrote in 1888, only months before his nervous breakdown, from which he would never recover).

Just as Nietzsche can only expose the false, metaphorical nature of language by resorting to metaphors, he can only expose Christian morality as a reality-denying fiction through the use of fiction. This is because an objective outside perspective on the web of lies and deception in which individuals are entangled is never immediately available. Therefore, instead of making a vain attempt to construct such a "truthful" perspective in his texts, Nietzsche appeals to what he alternatively calls his readers' aesthetic sense, their intellectual conscience, or their will to truth, provoking his readers, often through the use of irony, to see all their present values for what they are a constellation of lies and deception, daring individuals to overcome these lies in the present so that they may consciously create new values in the future.

## Nixon, Richard

As Richard Nixon sought, and subsequently won, a second term as president of the United States, he became embroiled in a massive scandal involving illegal practices during his reelection campaign. On June 17, 1972, five men with connections to President Nixon's re-election committee were caught breaking into the Democratic National Committee headquarters at the Watergate complex in Washington, D.C. This intrusion funneled responsibility directly to the president and was not the only improper or illegal campaign activity sanctioned by the Nixon administration. Formally known as the Watergate scandal, such wrongdoings from Nixon and his staff led to the president's resignation from office on August 9, 1974.

In an effort to gather intelligence from the Democratic Party's presidential campaign, the Nixon administration attempted numerous break-ins at their opposition's headquarters. The first, authorized by the Committee for the Re-Election of the President's general counsel G. Gordon Liddy, instructed a team to invade the Democratic National Committee (DNC) headquarters on May 26, 1972. By prearranging a dinner at the DNC complex, a group of hired burglars had access to the building and tried to obtain information from the Democrats. This was unsuccessful and required another effort.

The second break-in was made one evening later on May 27. Eight men were disguised as

Federal Reserve workers reporting to the Watergate complex. They dodged security and tried to breach the DNC facility's security system. However, the mission failed, as one trespasser did not have the correct tools to complete the break-in. The two attempts on the DNC center were documented solely by testimonies of the coconspirators. Evidence does not exist to verify that either of the failed entries actually occurred.

Members of the Nixon administration were dissatisfied with their futile breach of the Democratic Party and remained committed in their efforts to seize competitive information. Nixon's team was eventually successful on May 28, when a well-equipped unit of five men took photographs of various DNC documents. Specifically, snapshots were taken of a DNC contributors' list to enable Republicans to strategize toward obtaining more voter support prior to the November 1972 election. Intruders also wiretapped the phones of Democratic strategists during the break-in.

One of the phone taps was improperly executed at the DNC facility. This required another visit to the Watergate, which took place on June 17. While surveying the grounds, a member of the Watergate security force, Frank Willis, noticed that tape was covering the bolts of various doors in the building. He removed the tape and did not believe this to be a concern. However, Willis later made another search of the premises and noticed that the tape had been reapplied at approximately 1:00 A.M. Police were subsequently notified, and the authorities caught five men who were burglarizing the DNC headquarters. Virgilio González, Bernard Barker, James W. McCord Jr., Eugenio Martínez, and Frank Sturgis, along with head conspirators Howard Hunt and G. Gordon Liddy, were all connected to the series of intrusions on the Democratic Party. They were eventually indicted for conspiracy, burglary, and violation of federal wiretapping.

President Nixon denied any personal involvement in the scandal and maintained that no one in his administration had taken part in the illegal activities. Specifically, he stated, "I can say categorically that . . . no one in the White House staff, no one in this Administration, presently employed, was involved in this very bizarre incident." Several months passed while Nixon

*President Richard Nixon and First Lady Pat Nixon calmly sip coffee on the White House Truman Balcony on July 25, 1972, while allegations over the previous month's Watergate break-in continue to pile up. Denying any involvement in the phone tapping and break-in at the Democratic National Headquarters, Nixon was later found to have recording systems installed in the White House. The Smoking Gun Tape ultimately proved the president had lied to the nation, his closest aides, and his own lawyers for over two years.*

remained in office and legal action piled against the burglars who were caught at the Watergate complex. On February 7, 1973, the U.S. Senate established a committee to investigate the scandal as evidence of perjury arose from the court statements of the individuals who were charged with participating in the break-in.

The committee's investigators revealed that the president had recording systems installed in the White House. Special investigator Archibald Cox requested and eventually subpoenaed tapes from the Oval Office because he suspected that Nixon was hiding information about his involvement in the Watergate scandal. Nixon refused to release the tapes, declaring that his refusal was his "executive privilege" as commander in chief. He ordered Cox to terminate the summons, but after

Cox refused, the committee began investigating how to impeach the president.

On numerous occasions, Nixon was caught trying to remove members of his administrative staff who undermined his authority during the Watergate investigation. When this information became public, he lost political support and experienced heightened suspicion about his involvement throughout the scandal. In March 1974, the investigation reached a climax when legal action was taken against those who had broken into the DNC headquarters. A grand jury in Washington, D.C., named seven of Nixon's aides as co-conspirators to the scandal, and the president himself was called an unindicted co-conspirator by adjudicators.

This legal action forced the president to appease critics and appear as though he was working with

authorities. Nixon released several private recordings of his conversations with his counsel, John Dean. The tapes revealed the Watergate strategy, a plot to cover-up the break-in, and information about how Nixon's break-in crew was paid with "hush" money to keep quiet about the plan. The most damaging footage for Nixon, called the Smoking Gun Tape, was recorded shortly after the DNC facility break-in. It exposed Nixon's plan to cover-up the DNC intrusions and block an investigation of the raid. The president's lawyers confirmed Nixon's untruthfulness by finding that the Smoking Gun tape "proved that the president had lied to the nation, to his closest aides, and to his own lawyers—for more than two years."

Intense pressure and scrutiny forced President Nixon to resign from office on August 9, 1974, after learning there were enough votes in the House of Representatives to impeach him. Nixon strategically never admitted to lying. However, in hindsight it can be seen that his repudiation of personal involvement was false. The president deceived Americans trust and confidence that a political leader would not put his own personal and political gain ahead of his public duties. In sum, the combination of recorded evidence outlining the Republican plots against the DNC, and testimonies from the indicted burglars, provided enough evidence to conclude that Nixon's denials were fabricated.

## Nonverbal Cues

Nonverbal cues to deception refer to unique motor behaviors that occur when lying but are absent or present to a lesser degree when truth-telling. Nonverbal cues also include vocal behaviors separate from the content of the speech, such as vocal pitch. It is thought these cues are connected to the underlying cognitive and emotional demands of deception and so unintentionally reveal a liar's true beliefs. These cues may also, or instead, reflect the strategies that liars employ in an attempt to appear convincing. Whether unwitting or strategic, these behaviors vary depending on characteristics of the situation and of the individual. Consideration will be given to each of these topics, exploring how the emotional and cognitive elements of deception elicit nonverbal cues to their deceit, the situational and individual differences that modulate the cues to deceit, and the benefits of using nonverbal cues.

### Mental State of the Liar

Initial research into the nonverbal cues of deception was concerned with the notion that liars experience different emotional states than truth-tellers. Despite liars' best efforts, unintentional manifestations of emotions were thought to be observable in bodily behavior, often referred to as leakage cues. These cues are thought to reflect guilt associated with misleading another and anxiety about being caught. The leakage hierarchy hypothesis suggests that cues associated with these emotions are more likely to be expressed through bodily channels that are not as perceptually salient to a communication partner and thus not as closely monitored by the liar. As a result, leakage should be most evident in the movements of the legs and feet, followed by the hands, and less so in the more visible and practiced movements of the face. A critical

exception, according to Paul Ekman, a pioneer of the emotional approach to lie detection, are the fleeting and nearly indistinguishable emotional expressions that occur on the face while one attempts to suppress true responses. Commonly referred to as microexpressions, the evidence for their existence has been mixed, and even when isolated, they are often reported as being too scant for reliable use in practice. Other emotional displays have been found to be more reliable indicators. For example, liars tend to produce fewer genuine smiles than truth-tellers but attempt to compensate with feigned smiles.

Extending the emotional approach, the four-factor model proposes that liars must also contend with unique cognitive demands (along with greater overall arousal and the overcontrol of behavior). In many cases, deception has been shown to be more cognitively challenging than truth-telling: a false reality must be maintained while the ever-present truth competes for expression. Thus, when cognitive demands are present during deception, characteristic signs of cognitive load are revealed across a range of nonverbal behaviors, including decreased eye blink rates, greater speech hesitations, and a longer initial pause before beginning to respond. Recently, researchers have focused more sharply on establishing nonverbal cues to deceit that tap into the heavy processing demands, with less attention given to the nonverbal behaviors indicative of felt emotions. However, it is noteworthy that there is some controversy around the cognitive load approach, with some researchers arguing that the cues to deception should be expected to decrease when a person is mentally taxed.

### Deception in Context

There is no simple correspondence between the cognitive and emotional antecedents of deception and its behavioral consequences. In a review of 100 nonverbal cues to deceit, 75 percent of the behaviors investigated were not related to deception in any way. There is little evidence that any single nonverbal cue, akin to Pinocchio's growing nose, will accurately distinguish deception from truth across a range of individuals and situations. Lies vary dramatically, from outright inventions to subtle concealments, from mundane white lies to highly consequential deceptions, and from lying

for self-gain to lying for selfless reasons. The memory demands of inventing a lie, the emotional impact of highly consequential deceptions, and the social implications of lying for self-gain place various demands on the individual. By accounting for the differences in the type of lie told, reliable lie-dependent nonverbal cues can be discovered.

The cognitive demands associated with deception can be greatly minimized by rehearsal. For instance, there is a longer initial response time when lying. This is thought to reflect the processing time needed to either generate the lie or inhibit the truth. However, after rehearsal liars take a shorter time to respond than truth-tellers, reflecting the reduction in cognitive demand. Thus, police officers conducting street interviews moments after the crime will observe different indicators of deceit than would a police interviewer who interviews the suspect after they had been given time to prepare their account.

The emotional demands also vary by situation. When lying, people may experience diverse emotions, including fear of being caught, guilt associated with misleading another, or even enjoyment from having successfully misled someone. However, there are occasions when lying may be as emotional as telling the truth. According to studies in which people are asked to keep a record of their lies in their daily life, the majority of deception is relatively inconsequential, as most lies are told to protect another's feelings or to exaggerate one's own accomplishments. These deceptions are not fraught with fear of being spotted or with feelings of guilt for deceiving. Nonverbal cues to felt emotions may offer little advantage in this situation. In some situations lying can even be emotionally easier than telling the truth. For example, a teenager who deceptively says that he or she was studying at a friend's house might be telling a lie that is trivially easy when this is what the teenager's parents already assumed. Thus, liars need not experience the anxiety that is predicted to accompany deception.

Equally, truth-tellers may feel more apprehensive than may be expected because of the possibility of not being believed. Studies examining vocal cues of deception have shown that human lie detectors are able to recognize the apprehension

of honest speakers but often misinterpret this information as being deceptive, a phenomenon known as the Othello error. Thus, context not only influences the emotions experienced when lying but also when telling the truth. Any interpretation of nonverbal behavior must be done with an understanding of the context in which the behavior was produced.

### Interactions With Individual Differences

The context in which lies are told will influence the availability of nonverbal cues presented. There are also particularities of the person that influence the nonverbal display, such as working memory capacity and emotional control. Differences in motivation and confidence can also alter the naturalness of behavior. People who are too eager to appear believable will often exhibit actions that are overly deliberate, thereby producing behaviors that violate expectations of what is considered appropriate in a given situation. Conversely, those who are more confident and well practiced in their ability to lie do so with greater success.

There is mounting evidence that the latter is more common in everyday types of deception, where deception mostly goes undetected and reliable nonverbal cues for identifying deception are few. The self-presentational perspective supports this notion, arguing that liars are quite adept at regulating their behaviors by avoiding apparently suspicious behaviors and creating an impression of honesty. For example, deceivers who mimic the movements of their conversational partner are more readily believed, suggesting a simple behavioral adaptation that is tailored to project an honest demeanor.

There is of course an alternative explanation to low detection rates that has less to do with the individual skills possessed by liars but more with the inability of lie detectors in detecting deception. In a comprehensive study that spanned 75 different countries, people reported that the most revealing nonverbal cue in detecting deception is gaze aversion, a cue that has received little or no empirical support. However, followup research has shown that lie detectors rarely rely on these wrong beliefs when attempting to detect deception in real-time. Instead they are more sensitive to open-ended categories of others' perceived

incompetence and ambivalence. Thus, the self-presentational skills of individual liars, in more or less demanding situations, seem to best explain low detection rates.

The culture in which the individual was raised also influences their nonverbal behavior. Surinamese people make less eye contact than people in other cultures. Although it is not a reliable indicator of deception, conversational partners commonly link gaze avoidance to dishonesty. Cues that are more diagnostic of deception, such as decreased bodily movement, also differ by culture. Some research shows that African Americans move more overall than white people. Nonetheless, the differences in nonverbal behavior when people lie and tell the truth appear promisingly stable across cultures. Although African Americans may exhibit more movement, they show a reduction in that movement when they lie, as would people in other cultures.

### Benefits of Seeking Nonverbal Cues

Although nonverbal cues to deception are not highly reliable from one lie to another, with the proper controls and a clear specification of the conditions in which deception can occur there are advantages to using nonverbal cues as indicators of deceptive intent.

Nonverbal cues to deceit appear to be similar in the cultures that have so far been explored. Nonverbal cues span not only cultures but also time. One study found that over a two-year period nonverbal behavior remained consistent, while verbal behavior showed no such consistency. There also are cues that appear to be reliable relatively independent of context. For instance, whether rehearsed or unprepared, liars display an overall reduction in their bodily movement. Reduced bodily movement shows up in many studies using a range of lies. That is, there are cues to deceit that are diagnostic and potentially generalize across the various lies people tell.

Because truth-tellers tend to believe "the truth will come out," they typically do not regulate their outward appearance. When people lie it is thought they strategically control their movements in an attempt to minimize any cues. Ironically, this strategy gives liars away precisely because truth-tellers do not usually engage in such nonverbal self-control.

Although liars may strategically attempt to suppress cues to deceit, the interviewer can actively elicit them. One method requests interviewees to tell their stories backward. Deceivers find this difficult because the act of generating a false story depletes cognitive resources, leaving little cognitive capacity available to deal with reordering their tale. This has been shown to increase the nonverbal cues to deceit that are associated with cognitive effort.

Nonverbal cues also offer a direct benefit to the lie detector. The use of nonverbal cues is less cognitively demanding than processing verbal content. As such, this can free cognitive resources and aid a police interviewer, for example, in developing more effective questions for further probing as well as keeping in mind the facts about the case at hand. There may also be situations in which verbal communication is not possible, such as at an international airport, where nonverbal behavior may be the sole source of information; security officials need to decide who to search at customs and can only make this judgment from visual behavior. Bearing in mind the strategies liars use and the contextual and individual influences on behavior would serve security officials well.

## Normandy, Allied Invasion of

Allied forces invaded the beaches at Normandy, France, on June 6, 1944, surprising German commanders who anticipated landings at the Pas-de-Calais, France, the narrowest point of the English Channel. The success of the invasion followed years of British and American planning for Operation Overlord and two lesser-known cover efforts code-named Operation Bodyguard and Operation Fortitude.

In 1943, planners at the Supreme Headquarters Allied Expeditionary Force (SHAEF) realized that the German command would anticipate and plan for an invasion of Europe, so the Allies needed to influence German planning. The London Controlling Section commanded by Colonel John Bevan and the chief of staff of SHAEF, General Frederick Morgan, devised a deceptive invasion plan: Operation Fortitude, which shadowed the real Allied invasion plan. Allied planners sought to make the German command believe that the attack at Normandy was a diversion and the attack would come elsewhere. This would tie up large numbers of German forces and allow the Allied landings to get a firm hold on the beachhead before the Germans realized their mistake.

Operation Bodyguard was designed to tie up German forces in four separate areas so they couldn't group in one place. Allied diversions led Germans to believe that invasions would come in Scandinavia, the Pas-de-Calais, the eastern Mediterranean, and the south of France in the late summer and that the Allied priority was on air offensives.

Operation Fortitude South at Pas-de-Calais was created to appear as the real location of the

attack and to lead the Germans to believe that the Normandy landings were just a diversion. Allied planners used Ultra messages to confirm the successful acceptance of information by the Germans; Ultra was an intelligence program that enabled the Allies to decode and read German war communications. The diversion at Calais included false orders of battle and published division and corps dispatches of nonexistent airborne troops. A false First U.S. Army Group was activated under General George Patton, who was seen in public as often as possible.

German reconnaissance found dummy encampments along the east coast of England that included false radio traffic to attract German signal units, and fake equipment that looked like convoys and other heavy trucks. Additional bombing of the Pas-de-Calais area contributed to the diversion. These operations were collectively called Operation Quicksilver and effectively masked the real invasion forces building up in western England. The success of this operation was due to the inability of the Germans to verify by air reconnaissance the information they received because of Allied air superiority in Germany.

Phase two of the plan, Operation Fortitude North, involved making the Germans believe the invasion would take place in the Scandinavian countries. The Germans anticipated a landing in the autumn of 1944, and the purpose of this operation was to convince the Germans that a cross-channel invasion would not be attempted. Instead, Allied forces would move from the northern areas of Scotland and Ireland and invade German-occupied Norway. Agents also made sure that the Germans believed that Allied bombing runs had precedence over a land invasion. This operation was successful in that it kept over 300,000 Germans stationed in Norway until the end of the war.

Allied planners used double agents and translated messages to perpetuate the deception of Operation Fortitude on the Germans. The primary double agent used by the Allies, Joan Pujol Garcia, code-named Garbo, was a Spaniard who created his own network of agents. Two other agents who worked with the Double-Cross Committee included Tricycle, the code name for Yugoslav businessman Dusko Popov, and a Polish officer, Captain Roman Garby-Czerniawski, code-named Brutus. These three men kept the British informed

about German plans and the location of troops, while leaking information to the Germans about the Allied invasion plans. The role of the double agents continued after the invasion's success.

German commanders Gerd von Rundstedt and Wilhelm Keitel took the reports from the agents and tried to convince the high command of the dangers. They disagreed with the decision to spread the forces in four different areas that could not be reinforced. Adolf Hitler firmly believed that the invasion would come at Calais because of the narrowness of the channel and the convincing radio traffic picked up by German observers. Attempts were made prior to June 1944 to move some of the German panzer units closer to the coast, where they could more easily be called into service. However, Hitler ordered von Rundstedt to keep the bulk of the panzer forces near Calais, and only Hitler could order the panzers to another location.

### Successful Ruse

On the day of the invasion, the German command continued to believe the ruse that an invasion at Normandy was a diversion. They encountered miniature paratroopers designed to make noise and draw attention away from the real drop zones. Areas near Calais were bombed just as in Normandy to disable the railroads and to cause confusion.

However, the chief of staff of the German Seventh Army, General Max-Josef Pemsel, was in Normandy and notified General Hans Speidel and other superiors of the invasion. Pemsel assured them that they could reverse the Allied advances in Normandy because it was a small force. However, the Germans soon realized the actual size of the landing force and called for reinforcements. Von Rundstedt requested the reserve panzer units but was denied the request by General Alfred Jodl, who refused to wake Hitler from his nap. The panzer units were released late on June 6, but did not arrive until June 7 because Allied bombings impeded their travel. Once the units arrived it became apparent that a solid Allied beachhead was already established. German commanders also did not foresee the follow-up plan that included Allied landings in the south of France and forces commanded by General Patton. This, too, was part of the ruse of Operation Fortitude.

The success of the Allied invasion at Normandy relied on deceptive information put out by the Allies to mislead the German high command and war planners. Within Germany and France, false press coverage, information passed from double agents to members of the German high command who trusted their sources, and wireless communications between agents to their connections meant to be intercepted by the Germans all helped build the belief among German planners that the invasion would be in another location. The deception continued in England, with press coverage of General Patton, decoy military vehicles, false radio traffic, and messages sent from fictional units to command.

The ability of the Allies to verify German acceptance of the supplied information through the Ultra decoder confirmed the continued success of a carefully constructed operation. The deception carried out by the British preceding the invasion of Normandy helped bring about the invasion's success, while protecting troops being amassed in Great Britain. It is a deception the size of which could never be attempted again because of advances in technology and warfare that would lead to the endangerment of civilians and the military.

## Nostradamus

Michel de Nostredame (1503–66), more commonly known by the Latin form of his name, Nostradamus, was an apothecary, astrologer, and visionary (or seer), whose apparently prophetic writings have acquired a huge following of believers. His followers claim he was uniquely capable of seeing into the distant future and predicting events of global importance, such as, most famously, the Great Fire of London, the rise of Napoleon Bonaparte, the fall of Adolf Hitler, the Hiroshima bombing, the death of Princess Diana, and the September 11, 2001, attacks on the World Trade Center.

### Life of Nostradamus

Nostradamus was born and educated in the south of France. By all accounts his grandfather had been Jewish, later converting to Roman Catholicism, and the influence of more than one sacred narrative on the young Nostradamus is often regarded—largely because of the vague pronouncements of Nostradamus himself concerning his childhood—as formative. He appears, for instance, to have shown an interest in the Kabbalah as well as in such Christian scriptures as the Book of Revelation. A precocious scholar, he familiarized himself with Latin, Classical Greek (a much less normal academic achievement at that time than later), and Hebrew. He is also said to have demonstrated an aptitude for mathematics, an interest in the natural world, and a fascination with astrology.

His undergraduate studies in the liberal arts at Avignon, France, ended when the university was closed by an outbreak of plague, at which point Nostradamus set himself up as a traveling apothecary. He subsequently migrated to Montpellier, France but was expelled from its university owing (as he claimed) to the authorities' displeasure at discovering his history as a practitioner, rather than academic theoretician, of medicine. During the extensive travels which led up to this period Nostradamus specialized in treating plague victims, and in time he established a reputation as an effective herbalist, using natural cures such as the vitamin-rich "rose pill" (compacted from crushed rose hips) and an emphasis on basic hygiene, an approach that was opposed to many

of the kill-or-cure techniques used in medicine at the time.

In consequence, he became something of a regional celebrity and began associating with politically and culturally influential figures, such as the Renaissance scholar Julius Caesar Scaliger. Despite his training and experience in medicine, Nostradamus's interest in almanacs and books of prognostication continued to grow. Although he published medical treatises and commentaries, his transition toward occultism, and the published predictions which followed, would seal the destiny by which he has been known ever since.

### The Prophecies

His most famous work is *Les Prophéties* (*The Prophecies*). The first version of this almanac of predictions appeared in 1555, an expanded second edition was released in 1557, with a third and final edition published posthumously in 1568. The predictions are arranged in four-line verse stanzas (or quatrains), mostly in French, and mostly in rhyme. These are in turn organized in groups of 100, which Nostradamus calls “centuries.” The final edition of the *The Prophecies* contains 942 quatrains. Problematically, they are phrased in such a way that interpretation is left up to the reader and many widely differing readings have been offered; difficulty in interpretation is compounded because details are omitted and the text is intentionally vague, containing no dates and sowing confusion over verb tenses—past, present, and future.

Additionally, Nostradamus frequently departs from French, interspersing his verse lines with Latin, Greek, Italian, and the southern French dialect, Provençal. It is sometimes claimed that this vagueness is pre-emptive protection against charges of magic, diabolism, or witchcraft, although this issue is contentious. It is more possible that he assumed the guise of seer and prophet to provoke the respect and awe he coveted at key stages in the ambitious trajectory of his career.

Thematically, he tends to the apocalyptic and writes about disasters like droughts, fires, plagues, earthquakes, and wars, one reason, in all likelihood, for the hold his writings have established on the Western imagination for five centuries. From the outset his works generated a remarkable degree of attention, and his fame grew proportionately.

Michel de Nostredame (top) more commonly known as Nostradamus, was an apothecary, astrologer, and visionary who claimed a unique capability of seeing into the distant future. The *Prophecies* (bottom), a set of predictions written in four-line stanzas in French, first appeared in 1555.

After the publication of the first edition of the *The Prophecies* in 1555, for example, he attracted the notice of King Henri II's queen, Catherine de Medici, who appointed him to the royal court as physician-in-residence to her son.

The psychic methodology used by Nostradamus is unknown, although some theorize that he

used techniques of meditation involving ritual use of fire and a bowl filled with herbs and water. He may also have used his herbalistic expertise to create hallucinogens. In his writings he primarily employs astrological divination but also draws on the printed record in terms of classical, scriptural, and Apocryphal sources, as well as medieval chronicles, which are not always acknowledged.

### Current Interest in Nostradamus

The open-endedness, obscurity, and vagueness of his prophecies have led to the suggestion that anyone can read almost anything into them at will. Nostradamus does demonstrate an interest in repetitions and cyclical patterns in history, and it is therefore conceivable that the writings are a projection of these into future time. For their own reasons, many readers still opt to believe that Nostradamus's abilities were genuine and that he was writing in a predictive code, although within this constituency there is doubt over whether or not the meaning of the quatrains has yet been satisfactorily explained.

The desire to believe is, in turn, stoked by printed and online media devoted to the man and his works. There is a considerable industry concerned with popularizing and glossing Nostradamus's prophecies, yoking them unerringly to modern-day turmoil, catastrophes, and political events, and searching for retrospective validation of his claims. The authors of such books are addressing a lucrative market in fortune-telling, occultism, and new-age psychic phenomena, which is growing ever more sizeable in the Western world. These writers often claim that they alone have—for the first time—"unlocked" the seer's mysteries. The large number of popular works about Nostradamus may be held to obscure the research of more traditionally scholarly biographers and investigators, who find the task of separating fact

from fantasy increasingly challenging. In works which do not set out to popularize, skepticism if not incredulity is the prevailing response.

In any case, the penumbra of mystery and uncertainty surrounding Nostradamus's life and career has not been completely dispelled, despite a new quantity of verifiable biographical information which has emerged since about 1990. Almost every claim made for him has been met with a counterclaim. Sifting through these statements, however, the consensus is that Nostradamus himself believed his predictions point to a truth lying beyond them, which time would subsequently ratify. Academic researchers as well as the public at large remain fascinated by this claim, although definitive proof has never been supplied.

## Oaths

The oath is the antithesis of lies and deception. It is constructed as the “gold standard” of truth. According to the *Oxford English Dictionary*, an oath is “a solemn or formal declaration invoking God (or a god, or other object of reverence) as witness to the truth of a statement, or to the binding nature of a promise or undertaking; an act of making such a declaration.” An oath makes a promise inviolable by linking it to the actor’s most sacred loyalties. The basic structure is that a speaker swears, taking an oath confirming the truth of some assertion of fact by connecting it to a core value through language such as “as my witness” or “so help me.” The earliest reference to an oath is found in *Beowulf*; the device is found in many other literary works, including Charles Dickens’s *Dombey and Son* (1848): “But I could take my oath he said . . .”

As a matter of philosophy, the oath is a representation of speech act theory. The core premise of this theory is that, under the proper conditions, to say is to do. The classic examples are saying “I do” at the front of a church, which means that you are married, or saying “I bet” under the right conditions when someone else responds. “You’re on” means that a wager has been made, and at the end of a contest money is going to change hands. The core notion here is that talking is

commitment. An oath is a very powerful example of that commitment.

The notion of a promise underlies much of social organization. Individuals need to be able to depend on one another’s word to function as a society. In law, the promise takes the form of a contract, which binds two parties to mutually defined actions and specifies penalties for failure to comply. The oath is the premier form of a contract; individuals give their word, backed by their devotion to a sacred object or relationship, that they are speaking the truth.

Anything humankind can construct, however, it can also pervert. So oaths can be broken, or oaths themselves can be used for antisocial purposes. The former case, when it happens in court, can result in charges of perjury or obstruction of justice, in which serious criminal penalties result from conviction. The North Carolina General Statutes define perjury this way: “If any person shall willfully and corruptly commit perjury, on his oath or affirmation, in any suit, controversy, matter or cause, depending in any of the courts of the State . . . every person so offending shall be punished as a Class F felon.” The presumptive sentence for someone with no prior convictions is 13 to 16 months. The legal system takes seriously the need for honest testimony under oath.

The Mafia and other fraternal forms of organized crime are said to promote a particular sort of

oath: Omerta, or the code of silence. Under these rules, Mafiosi are never to cooperate with law enforcement or any other form of authority, even in naming the individuals who attempted to kill them in a daylight attack. Under this approach, honor requires organizational members to take revenge for themselves through the mechanism of the vendetta but never to involve agents of the state. This mechanism, too, is a sacred vow, though it is oriented in antisocial ways. As with other oaths, it is a valued mechanism for preserving the disciplinary tenets of an institution.

Experts trace the notion of an oath to the Book of Genesis (8:21), in which God promises to “never again” curse the ground because of humans nor destroy all living creatures as he had done in the flood. “Never again” is defined as an oath through the Talmudic tradition. That phrase is recognized in a modern context as a statement in response to the Holocaust, intended to promise that those horrors will not be repeated. Some religious traditions decline to take oaths based on their readings of scripture. The U.S. Constitution makes provision for citizens to “affirm” their statements in lieu of taking an oath that would offend their religious tenets.

U.S. history includes a prominent encounter with loyalty oaths. President Harry S. Truman established a loyalty program that included an oath. This movement was a reaction to the actions of U.S. Senator Joseph McCarthy and the actions of the House Un-American Activities Committee. The oaths were enacted by various states for public employees and upheld by the U.S. Supreme Court in *Garner v. Board of Public Works* (1951). The court has generally upheld state loyalty oaths as reasonable conditions on employees, despite civil liberties advocates’ assertions that these sworn statements interfere with the freedoms of association and expression.

The irony of loyalty oath requirements is that the only people who would run afoul of these rules would be people who objected to them on principle and refused to comply in order to make their point. Anyone bent on espionage or other efforts to subvert the government would blithely sign the oath and go on with his or her nefarious actions. Therefore, the imposition of loyalty oaths is a symbolic battle between forces of conformity and individuality, not an exercise

likely to distinguish between loyal citizens and saboteurs.

## Operation Bodyguard

Operation Bodyguard was the code name given to the Allies’ plan to convince Adolf Hitler that the invasion of western Europe would take place at the Pas-de-Calais, France, while planning the actual invasion (Operation Overlord) for Normandy. In order for the plan to succeed, the Allies tricked the Nazis through the use of fake armies, dummy landing craft, and false intelligence. The D-Day invasion of Normandy, beginning on June 6, 1944, was one of the most successful military operations of World War II. One million men and thousands of ships and aircraft from around the world combined to form the largest joint military operation in history. On the first day, more than 5,000 ships would carry more than 200,000 Allied troops to Normandy, the largest amphibious operation in military history. This would lead to the opening of the second front in the war against the Nazis and would result in the collapse of the Third Reich less than a year later.

However, the D-Day operation would not have been successful without the incredible deception efforts undertaken by the Allies. The effort was based on the Allies’ belief that the Axis powers, notwithstanding their near total domination

A graphic from a scrapbook prepared for Lt. Gen. Hoyt Vandenberg, commander of the 9th Air Force from August 1944 to the end of the war, shows a detail from Operation Bodyguard. The enemy was led to expect an invasion in one area (Pas-de-Calais, France) while the invasion was actually scheduled for Normandy. In addition to attacking key sites in the Normandy region, 9th Air Force aircrews flew many missions against the Pas-de-Calais to support the deception that the Allies intended to land there.

of Europe, would be unable to defend all of the 3,000 miles of coastline, stretching from Norway to France, under their control.

Operation Bodyguard had two goals: first, to weaken Hitler's "Atlantic Wall" by causing its defenses to be stretched even thinner than they were, and second, to convince the Nazis to concentrate their forces at a false invasion spot. Also, after the D-Day operation began, the continuation of Operation Bodyguard's activities were intended to convince the German military that Normandy was only a diversion, as the real invasion would be launched elsewhere. The name for the operation comes from a speech given in 1943 by Winston Churchill, prime minister of Great Britain, in which he stated: "In wartime, truth is

so precious that she should always be attended by a bodyguard of lies."

### The Double-Cross System

Critical to the success of the operation was the Double-Cross System developed by the British in 1941. Captured German spies (or those who turned themselves in) were interrogated by M15, the British intelligence agency. Those who were deemed suitable were given the opportunity to become double agents for the British. Initially, the double agents would be given accurate information to send back to German intelligence agencies. This information was often insignificant or, in some cases, communications were delayed so that German intelligence would receive

important intelligence too late. Notwithstanding the untimely receipt, the double agents' credibility with their German handlers was often enhanced by the accuracy of their reports. A notable example of this was the accurate (albeit late) intelligence given to the Germans about Operation Torch, the joint British-American invasion of north Africa that took place in November 1942. The British knew that their efforts were succeeding because they had deciphered the German codes.

The Double-Cross System was used to protect the D-Day invasion. Agents were given a combination of real and false information to report to the German intelligence services. Based on these reports, German intelligence concluded that the main invasion would be at Calais. Even after the Normandy invasion began, German intelligence remained convinced that the real invasion was still going to be launched at Calais.

### **Dummy Military Operations**

One of the goals of Operation Bodyguard was to convince the Germans that Allied military strength was actually greater than it was and that the Allies were capable of mounting two large-scale operations against Hitler's Atlantic Wall defenses. Operation Bodyguard was actually divided into two operations: Operation Fortitude and Operation Zeppelin. There were two elements to Operation Fortitude. First, there was a phony joint American-Anglo-Russian invasion of Norway in order to keep in place the 464,000 German troops occupying Norway. This assault would be launched by the fictional Fourth Army Group that was headquartered in Edinburgh, Scotland. British General Andrew Thorne, who had been the British military attaché in Germany during the 1930s and knew Hitler, was appointed "commander" of this group. The troops that made up this rump army were led by another British officer, Colonel R. M. MacLeod. The dummy Fourth Army, according to William B. Breuer, was supposedly composed of "some 250,000 men with their own tactical air force and 250 tanks and armored vehicles" but was in fact nothing more than Colonel MacLeod, several other officers, and roughly 20 radio operators.

Another part of the deception was diplomatic communications between the Allies and Sweden. Sweden was neutral during World War II,

but the diplomatic communications between the Allies and Sweden made it appear that an Allied invasion of Norway was imminent. When this information made its way to German intelligence and German diplomats, it only reinforced the belief that the Allies were planning an invasion of Norway.

A second element of Operation Fortitude's deception was the invasion route across the Pas-de-Calais, or as the English referred to it, the Straits of Dover. Gerd von Rundstedt, the commander of German forces on the Western Front, was convinced that this would be the invasion route as it was the shortest distance (22 miles) between Great Britain and France. The invasion was to be mounted by a dummy First U.S. Army Group, which the Germans were led to believe would be made up of more than 1 million men led by General George S. Patton. The Germans held Patton in such high regard that they believed he was the only general capable of leading the invasion; they referred to his "army" as Army Group Patton. Patton contributed to the deception by making speeches throughout England as the commander of the First U.S. Army Group.

The German High Command was so convinced that the main Allied attack would be mounted by what turned out to be a phantom army that German forces were not redeployed from Calais until seven weeks following the June 6, 1944, D-Day invasion, as Hitler refused to believe that Normandy was anything more than a diversion intended to lure the German 15th Army away from the real invasion. To further this deception, radio communications led the Germans to believe that the First U.S. Army group would be attacking in mid-July. Contributing to the ruse were the British and American motion picture industries. Special effects workers created dummy barracks, oil dumps, tanks, airplanes, Jeeps, landing craft, and any other equipment that a real army would possess. These wooden and rubber dummies were then set just as the real equipment would have been arranged. Therefore, German reconnaissance planes would believe that the fake equipment and armies were real. Even bombing operations contributed to the deception, as the Calais area was the target of more bombing missions than Normandy in the weeks prior to the invasion.

Operation Zeppelin was a plan to convince Hitler that an attack would be mounted by a phantom British 12th Army against the Axis' Balkan allies: Bulgaria, Hungary, and Rumania. The purpose of this fabrication was to freeze German troops in place to defend Hitler's Southern Front. To heighten the threat, the Allies leaked the story that Patton was assembling an army that would attack Trieste, Italy. The allies were so successful at this scheme that the Germans sent infantry and tanks from coastal defenses in France to Hungary and, in July 1943, briefly sent the "Desert Fox," Field Marshal Erwin Rommel, to Greece to command German Army Group E. Rommel would eventually be sent to Normandy (in November 1943) to take command of the German defenses there. Patton would ultimately be sent to England to command the dummy First U.S. Army Group, the force the Germans believed would invade Calais.

### Conclusion

Operation Bodyguard was a critical element in the success of Operation Overlord—the Allies' opening of the Western Front. The deception forced the Germans to divert forces away from Normandy in the weeks before D-Day and convinced them to keep those forces in place to await an attack that would never come.

## Operation Mincemeat

Winston Churchill said of wartime deception and espionage: "In the higher range of Secret Service work the actual facts of many cases were in every respect equal to the most fantastic inventions of romance and melodrama." In April 1943, Churchill, the prime minister of Great Britain, gave approval for an elaborate deception program, Operation Mincemeat, on the condition that General Dwight Eisenhower would approve the plan, which the American commander quickly did.

Operation Mincemeat was a plan by British intelligence to arrange for the body of a British Marine officer to wash up on a Spanish beach, the apparent victim of an airplane crash in the Mediterranean. The officer would have a briefcase chained to him, and in it would be letters between generals that obliquely suggested the Allies' next invasion targets. British intelligence hoped that the briefcase would come to the attention of German intelligence operatives, who were rife in that part of nominally neutral Spain.

According to the plan, the German spies would investigate the military briefcase, find the letters, and take the bait; access would come from the spies' close cooperation with Spanish officials, assured by a mixture of political affinity and bribery. After the covert copying, Spanish officials would return the dead man's effects to British authorities. Then German agents would pass the information on to Berlin. If top German analysts believed their "find," they would alter their strategy and staffing, moving resources to Greece and Sardinia, the letters' nominal targets. These actions would leave fewer defenses in

Sicily, described in the “discovered” letters as the Allies’ cover target but, in fact, the genuine invasion target.

Mincemeat’s deception succeeded in spite of universal agreement on the logic of Sicily as the Allies’ next step after the North Africa campaign. Churchill observed: “Everybody but a bloody fool would know it was Sicily.” And yet with an imaginative plan and the expenditure of only 200 pounds, members of British intelligence, diplomats, double agents, ordinary civilians, and the Royal Navy fooled the German intelligence hierarchy. The plan was designed to exploit the two major flaws that Admiral John Henry Godfrey, Britain’s director of naval intelligence, identified in spies: wishfulness and yes-manship. Mincemeat’s deception enabled Allied forces to take Sicily with a force of 160,000 men in 38 days with only 7000 casualties. Original estimates anticipated a 90-day campaign and much higher losses.

From Sicily, the Allies rolled up Italy: Benito Mussolini resigned, and Italy got out of the war. Because of the invasion, Adolf Hitler suspended Operation Citadel with 900,000 troops and 3,000 tanks poised to retake Russian territory, and sent its panzer units to Italy. This action was the blitzkrieg’s first failure and marked the beginning of the end on the Eastern Front.

### The Men Behind the Operation

Godfrey noted that deception requires a “sort of corkscrew mind.” Those minds must be top-notch, Godfrey added: “It is quite useless, and in fact dangerous to employ people of medium intelligence. Only men of first class brains should be allowed to touch this stuff. If the right people can’t be found, better keep out altogether.” Among the other top-notch minds working for Godfrey was Ian Fleming, who would gain fame as the creator of superspy James Bond; among his colleagues were men who became the models for Bond staples: the administrator M and the gadget-master Q.

Operation Mincemeat originated in two top-notch minds. Charles Cholmondeley (pronounced “Chumly”) was a 25-year-old flight lieutenant from the Royal Air Force assigned to MI5, the British Security Service. At 6 feet 3 inches tall and with poor eyesight he was not destined to be a

pilot; his work in military intelligence was outstanding. He was a fount of ideas, many exotic or unworkable, “but every now and again quite brilliant in their simplicity.” His complement was Ewen Montagu, a brilliant 38-year-old barrister gifted in analysis of opponents’ strategies. He led Section 17M, distributing naval decryptions of German coded messages from Bletchley Park and running double agents. Godfrey judged Montagu’s group “a brilliant band of dedicated war winners.”

These two imaginative intelligence officers found a body, crafted a backstory for the fictional Major William Martin, arranged to preserve the body for three months, and transported it via special canister aboard a submarine. They navigated the intelligence bureaucracy for plan approval; assisted in crafting credible letters; and created ticket stubs, receipts, and other “pocket litter” to be found with the body. Every item had to ring true when scrutinized by world-class intelligence agents wary of “plants.” Any error could destroy the plan; Germans would reinforce Sicily, meaning higher Allied casualties and possible mission failure.

### Later Accounts of the Operation

Operation Mincemeat became famous in a 1953 book by Montagu, *The Man Who Never Was*. It was first serialized in the *Sunday Express* under pressure from authors mounting their own versions. A thinly veiled fictionalized account, *Operation Heartbreak*, was published in 1950 by former cabinet minister Duff Cooper. Eventually the Joint Intelligence Committee (JIC) gave Montagu permission when the release appeared inevitable. Under JIC guidelines, he was not to explain how the dead body was acquired, give its identity, show how Britain had deceived Spain, or call attention to Spain’s collaboration with Germany. Montagu’s book has never been out of print since it was first issued. In 1956, a film with the same title debuted; it won the year’s award for best British screenplay. Popular acceptance of the story was demonstrated in 1956, when it was the basis for an entire episode of the British madcap radio comedy *The Goon Show*. Most of public understanding of Operation Mincemeat comes from the idealized and sanitized version Montagu rendered under the scrutiny of the JIC.

In 2010, a new and comprehensive examination was published by Ben Macintyre titled *Operation Mincemeat: How a Dead Man and a Bizarre Plan Fooled the Nazis and Assured an Allied Victory*. While researching a book on a World War II spy, Macintyre had come across a second book by Montagu, *Beyond Top Secret Ultra*, published in 1977. In it, Montagu mentions that he was “allowed to keep” some intelligence materials because of “special circumstances.” Macintyre assumed that was an allusion to Operation Mincemeat. After Montagu died in 1985, Macintyre set out to find the materials. Montagu’s son was the keeper of these records and allowed Macintyre access, providing the basis of his detailed re-examination of the Mincemeat saga. This volume includes more extensive photographs and copies of original reports than Montagu’s 1953 book.

Macintyre explains how a body was acquired to become Major William Martin; Montagu had used a cover story to obscure original issues. In fact, the body was that of Glyndwr Michael, a down-and-out Welshman who committed suicide in London. Macintyre illuminates the complex world of British and Spanish relations, which was manipulated as British intelligence worked to get German agents to take the bait after Martin’s body washed up. He also suggests that German intelligence operations, specifically chief analyst Lieutenant Colonel Alexis von Roenne, may not have been fooled by the materials but went along with lower-level analysts to placate and eventually weaken Hitler. This analyst, once Hitler’s favorite, was tried and executed after the attempt on Hitler’s life, not for involvement but because of his friendship with some conspirators.

Operation Mincemeat is a famous textbook example of deception in warfare. The account from Montagu and the updated and expanded treatment from Macintyre document the intricacies of this operation.

## Operation Neptune

Operation Neptune is the covert name given by the U.S. military to its landing operations at Normandy during World War II. After the war began, Germany occupied northwestern France in early 1940 after invading the area. Adolf Hitler knew that Allied forces were bound to appear on the scene after his actions, but he believed the ends justified the means. Not knowing when or where the Allied forces would attack, Hitler quickly appointed Erwin Rommel to lead German efforts in the region. As the initial defense, Rommel opted to finish the Nazi’s Atlantic Wall, an over two-mile-long wall on the coast with bunkers and other fortifications.

As Hitler had predicted, Allied forces wasted little time in beginning to strategize on how to most efficiently and effectively make inroads toward recapturing France from Germany. The landings began on D-Day (June 6, 1944) at approximately 6:30 A.M. Operation Neptune remains one of the most successful military operations undertaken by the U.S. military in its history. Just over two million men and thousands of planes and ships came together for a joint military action aimed at deterring further advancement by Hitler and Nazi Germany throughout the European continent.

While there have been immeasurable writings based on the activities at Normandy, few have actually discussed the amount of deception that went into making the operation successful. To some degree, this is because the information was not publicly available until the 1970s, when the British press began seeking access to information. After 1977, when the British government

chose to release a large volume of classified information, the world began to see the deception employed by the Allies in their efforts to bring down the Third Reich.

### Two Phases of the Invasion

There were two phases to the landings on Normandy. The initial wave consisted of just less than 25,000 troops, composed of British, American, Canadian, and French pilots, who invaded by air, which was followed by an amphibious landing of infantry and armor about six hours later. Without the element of surprise provided by horrible weather and planned deception for months leading up to D-Day, the mission would have likely failed, or at least been significantly less effective. Operation Bodyguard was a key piece of the surprise. Its mission was to distract German authorities as much as possible from believing Normandy was a likely invasion point. The goal was to get Germans (especially Hitler) to believe that any landing would occur at the Pas-de-Calais, France.

The Allied forces were led by General Dwight Eisenhower of the United States; ground forces were directed by General Bernard Montgomery of Great Britain. Before the Allied forces went into action, Eisenhower declared to them the following:

Soldiers, Sailors and Airmen of the Allied Expeditionary Force! You are about to embark upon a great crusade, toward which we have striven these many months . . . The eyes of the world are upon you. The hopes and prayers of liberty-loving people everywhere march with you. In company with our brave Allies and brothers in arms on other fronts, you will bring about the destruction of the German war machine, the elimination of Nazi tyranny over the oppressed peoples of Europe, and security for ourselves in a free world.

Through these words, Eisenhower hoped to explain why the invasion was so important. Further, looking back, his words clearly explain why it was so important for Allied forces to use as much deception as possible. The mission was extremely dangerous and important to the future of the West.

### Use of Deception

Under Operation Bodyguard, Allied forces had created a comprehensive series of deceptions, which helped guarantee that the landings came as a surprise to Germany. Underneath Operation Bodyguard was Operation Fortitude, which had three main divisions. Operation Fortitude North involved the threat of a Norway invasion with a follow-up attack of Germany coming through Denmark. Operation Fortitude South brought forth rumors of a fictitious invasion directed against Belgium and northern France through the Strait of Dover. Operation Fortitude South II was radio deception conducted after D-Day, aimed at getting Germans to believe that Operation Neptune was only a distraction for the real invasion, which was yet to occur.

Operation Fortitude South II was especially significant for Allied efforts after landing at the five beaches throughout Normandy. Hitler fully believed that Operation Neptune was a diversionary tactic, and as a result he refused to send additional troops to Normandy. This decision gave Allied forces a head start on their mission and put the Germans in an insurmountable deficit later in the war.

Operations Glimmer and Taxable also proved to help sell Operation Neptune. In these two missions, bombers flew patterns over the Strait of Dover and dropped aluminum strips. As the strips fell, they looked like a large fleet of planes moving on German radar. This finding only further cemented in Hitler's mind that Operation Neptune was neither the major Allied landing site nor operation.

Other tactics were utilized to assure the deception. These included numerous pieces and types of fake equipment, a phantom army led by General George Patton that was to be based in England, double agents, and fake radio transmissions. Dummy tanks and troop camp facades were constructed. German planes were permitted to photograph the design and implementation of these fake elements being built in southern Britain. Allied forces were cunning enough to use double agents to convince the Germans to attempt to decode white noise. While there was no real reason for doing this, it kept German intelligence officials focused on something besides the Allied-planned Operation Neptune. This was the key to all Allied

deceptions. They did not need to completely fool the Germans; instead, they needed to distract them and force them to split their energies and efforts.

While there is no guaranteeing which elements ultimately led to Hitler being deceived, it can be safely said that collectively the acts of deceit helped assure Allied victory over Hitler and the Nazis. For Operation Neptune to go as well as it did, the Allied forces first needed the weather to cooperate. It did. With Nazi forces believing that no attack could be launched where they believed one was coming because of the weather, their guard was down and their troops poorly positioned to combat a Normandy landing. Further, the Allied forces needed the Nazis to attempt to defend multiple potential attack sites, which they did. If the German forces were spread across multiple areas, there would be less initial resistance to the D-Day invasion. This was important considering the vulnerability the Allied forces would face while undertaking the initial invasion and subsequent trudge toward the enemy.

By June 30, 1944, Operation Neptune was complete. A secure foothold had been established in Normandy, which positioned Allied forces well for further advancement and eventual victory in World War II. If not for the well-strategized deception techniques instituted by American and British intelligence officers and soldiers, the war could have turned out quite differently.

## Operation Quicksilver

World War II was an international war conducted between 1939 and 1945 that involved most of the countries of the world, including all of the major powers at the time. Ultimately, the two sides of the war were classified as the Allies (anchored by the Americans and the British) and the Axis (powered mostly by Nazi Germany and the Japanese). As would be expected in an event called a world war, all of the countries involved placed their entire societies into the war efforts domestically, as manufacturing and technology became geared entirely toward achieving victory. Ultimately, the Allied forces were able to be victorious, defeating enemies in both the European and Asian theaters. The war came at a cost, however: the Holocaust, nuclear weapons at Hiroshima and Nagasaki, and tens of millions of fatalities all occurred over the time span of the war.

Operation Quicksilver was a major element of the Allied victory in World War II, which focused on deceiving Axis forces (particularly Adolf Hitler) in the European theater. Quicksilver was a subprogram attached to Operation Fortitude South, which was launched in 1944 to help detract German attention from the planned invasion on the beaches of Normandy. Ultimately, the goal of Operation Quicksilver was to convince Axis leaders that any American invasion would occur at the Pas-de-Calais near the Strait of Dover. By creating such deception, Allied forces hoped to ensure their victory by limiting the presence of Axis forces in the area of Normandy. The plan was thought up by David Strangeways, a colonel in the British Army who was a specialist in military deception.

#### Strategy and Tactics

The primary tactic of Operation Quicksilver was the creation of a fake element of the U.S. Army. German leaders—including Hitler himself—were, over time, convinced that there was an American Army group preparing to land in the Pas-de-Calais for the major invasion that had long been expected. The group, fictitiously called the First U.S. Army Group, was allegedly training under General George Patton in the United Kingdom while finalizing details of the invasion. The key player in the scheme was

Joan Pujol Garcia. He was a double agent loyal to the Allies who supplied the Germans with all of the detailed information created by the Allied forces to help steer the Axis leaders away from the Allies' actual plans.

Operation Quicksilver focused on utilizing fake radio signals to show Allied forces in southeast England preparing for a massive invasion. Likewise, double agents such as Garcia were depended upon to add credence to the fake plans with Axis officials. Aware that German officials would be suspicious of getting too much direct information, the Allies were strategic in permitting agents to only report on minor, secondary details. But they provided so many secondary details that, when considered together, Axis leaders had no choice but to believe the Allied forces were in fact going to come aground close to Dover instead of Normandy.

Reports provided to Axis leaders suggested that there were many troops located in south

central England, very few in the southwest, and the fake groups in the southeast. By creating such reports, it painted a picture for the Axis that the Allied forces were likely to attack from the southeast because that was where the largest number of forces and subsequent activity were reported. Through the German battle order that was prepared in response to Operation Quicksilver, attention turned toward Pas-de-Calais, just as the Allied forces had hoped it would.

### Six Subprograms

There were six major subprograms involved in Operation Quicksilver. Quicksilver I focused on the main, underlying idea behind the operation. The First U.S. Army Group, which was allegedly based in southeast England, planned to land in Pas-de-Calais because Axis troops (mainly German reserves) were being directed toward Normandy. Quicksilver II focused on radio communications as a means to divert attention toward

*German forces listen in on radio transmissions during World War II. In 1944, Operation Quicksilver utilized fake radio signals to create the deception that Allied forces were in southeast England, preparing for a massive invasion of the French coast close to Dover, England, when in fact they were secretly planning to invade Normandy. Double agents were used to add credence to the fake plans. The Allies "leaked" enough secondary information to create a puzzle that the Germans would put together and conclude was genuine.*

Pas-de-Calais. The goal was to use radio reports of unit movements from true locations to their place in England to prepare for the invasion. Quicksilver III involved the creation of dummy materials to provide aerial photographs in order to convince the Axis countries of the impending invasion from the north. The key facets of this subprogram were dummy landing crafts and simulated wireless traffic.

Quicksilver IV was the fictitious invasion plan that centered on bombing the beach area of Pas-de-Calais and railways in the area in the days preceding the Normandy invasion. The hope was that these activities would lead Axis leaders to move troops and supplies toward Pas-de-Calais and away from Normandy. Quicksilver V involved increasing as much activity as possible around Dover to make it seem that a build-up of troops and supplies was occurring in order to launch a successful invasion. And lastly, Quicksilver VI used increased lights at night to make it appear that there was activity occurring around the dummy landing craft created in Quicksilver III. When taken together, the six subprograms helped assure that Normandy was not the center of Axis attention, making D-Day an easier invasion than it otherwise would have been.

### Conclusion

How convincing was Operation Quicksilver? Even after D-Day had happened, Hitler and Axis leaders opted to keep over a dozen divisions (equating to hundreds of troops) behind at Pas-de-Calais in order to protect the region if Normandy was in fact a distraction for the real invasion. Operation Quicksilver had been developed to also convince Axis forces that the anticipated invasion would happen later than expected. The hope was that through this strategy, even if Normandy had been discovered as the actual invasion spot, the timing would have still come as a great surprise.

Many historians have incorrectly claimed that the true deception was the creation of dummy artillery aimed at providing visual cues to Axis aerial photographers. But at the time these events were occurring, German planes were unable to undertake reconnaissance missions over the United Kingdom, meaning they would have never seen the dummy equipment. The deception ran

far deeper and was far more sophisticated than anything that could simply be viewed from above.

## Othello Effect

A common mistake in lie detection is to interpret signs of nervousness too readily as diagnostic of deception. This misattribution phenomenon is known as the Othello error and is particularly prevalent in lie detection tools that consider stress as indicative of lying. The stress-based approach is problematic and prone to the Othello error, as truth-tellers may also experience stress. Lie detection that departs from the different cognitive states of liars and truth-tellers may be less prone to the Othello effect.

The term *Othello error* was coined by emotion theorist Paul Ekman, who took the name from William Shakespeare's play *Othello, the Moor of Venice* (written c. 1603–04). The play provides an excellent and famous example of misinterpreting nervousness as a signal of deception. Othello falsely accuses his wife Desdemona of having an affair with his lieutenant Cassio. Desdemona denies this charge and asks to summon Cassio, so he can testify to her truthfulness. When Othello tells her that he has already murdered Cassio,

Desdemonia realizes that she cannot prove her innocence and cries out. Othello misinterprets this emotional outburst as evidence for her treachery and kills her too.

The Othello error is a common occurrence in traditional lie detection, which departs from the stress-based approach to lying. This approach assumes that liars will be more concerned and nervous than truth-tellers. This nervousness is expected to shine through in behavioral cues such as gaze aversion, moving around, and increased fidgeting.

The control question polygraph test also departs from the idea that liars' fear of being caught will elicit marked physiological arousal. The problem, however, is that truth-tellers may also be aroused when accused of wrongdoing. Lie detectors can accurately pick up signs of stress but cannot determine the origin of the stress, making them prone to the Othello error.

With a false positive rate in the 16 to 35 percent range, the Control Question polygraph test is vulnerable to the Othello error. With regard to nonverbal lie detection, meta-analyses have shown that signs of nervousness, such as increased fidgeting, moving around, and avoiding eye contact, are not reliable cues to discriminate liars from truth-tellers. However, the belief that these nervous behaviors do correlate with deception is tenacious, not only among lay persons, but also among professional lie catchers. Police manuals, judges, and trainers sometimes advise observers to pay attention to cues that signal nervousness when attempting to detect deceit. The use of such invalid cues helps in understanding why people are bad lie detectors and are prone to the Othello error.

The chance of making the Othello error is especially problematic in high-stake situations, such as the courtroom. Facilitated by high levels of motivation, jurors and judges often get into a mode of tunnel vision, thereby overvaluing information in favor of their first impression of a suspect's trustworthiness and putting too small a price on disconfirming or ambiguous information. As an example, imagine an innocent suspect whose face is instantaneously assessed as being untrustworthy by the judge based on certain physical characteristics. When the suspect later bursts into tears while denying his guilt, it is not unlikely that

his tears will be interpreted by the judge as crocodile tears, in line with his bias.

Several solutions have been proposed to reduce the chance of committing the Othello error. A first solution takes the form of a guideline for observers. Lie detectors should be stimulated to avoid tunnel-vision thinking and to be cautious when interpreting cues that signal nervousness. They should keep in mind alternative explanations that may have evoked the very signs they use to infer deception.

Second, some tests provide safeguards against the Othello error. The concealed information test, for instance, assesses recognition of critical crime details by providing the examinee with the crime detail among a number of equally plausible alternatives (for example, "Was the victim killed with a gun? A knife? A rope? A bat? A screw driver?"). Research confirms that the concealed information test is unlikely to lead to an Othello error.

Third, in the field of verbal and nonverbal lie detection, the cognitive approach on lying has recently been promoted as a way to reduce the impact of the Othello effect. The approach is based on the notion that lying is cognitively more demanding than truth-telling. Observers should therefore pay attention to cues that signal mental effort, such as fewer movements, slower response times, and inconsistencies.

Observers have been shown to better discriminate liars and truth-tellers when they have to indicate how hard the suspects are thinking compared with when they are explicitly asked who is lying. While cognitive cues seem to be more reliable than cues of nervousness, cues are often shallow and small in number. Researchers have therefore suggested increasing the cognitive load, for instance, by asking the interviewees to tell their stories in reverse chronological order. Imposing mental load has shown to improve the observers' classification of liars and truth-tellers. However, one can imagine that such manipulation is also mentally demanding for truth-tellers, and it needs to be established whether imposing cognitive load not only increases the detection of liars but also comes with the cost of increased chance of an Othello error.

In short, falsely accusing innocents can be considered one of the major concerns about lie detection. Yet many lie detection techniques suffer from

high false-positive rates because they assume that signs of stress are solely exhibited by liars. Possible ways to reduce this Othello effect are to be open-minded and consider alternative hypotheses for the nervousness displayed by interviewees, to detect memory instead of lying by assessing the Concealed Information Test, or to depart from a cognitive approach to lying when detecting deceit.

## Overconfidence

Overconfidence is an inflated self-assessment of one's knowledge, answer, or estimate on a task. It is a bias in which a person's subjective confidence of performance is greater than his or her actual performance. This is in contrast to calibration, in which subjective confidence matches accuracy or performance.

Overconfidence has been studied in two distinct ways, either as overestimation of knowledge or performance (overestimation), or as excessive certainty that one's estimate or answer is correct

and accurate (overprecision). For example, if a student estimates he or she scored 90 percent on a test but actually scored 75 percent, the student is overconfident through overestimation. With overprecision, a student would create intervals that they are 90 percent confident contain the correct answer, and research with overprecision has found that people create intervals that are too narrow.

Overconfidence is often undesirable because it causes decision makers to underestimate obstacles, to fail to engage in proper preparation and information gathering, or to fail to seek out information contrary to their knowledge. However, overconfidence can be beneficial for increasing persistence in a course of action in the face of failure or in persuading other people about the accuracy of one's ideas. Generally, overconfidence is seen as a form of self-deception or illusion that people sincerely believe, but in certain cases confidence can be strategically and deceptively inflated.

One traditional way of studying overconfidence in the laboratory is by having people answer general knowledge questions (for example, what was Martin Luther King, Jr.'s age at death?) and providing a range that they are 90 percent confident contains the correct answer (overprecision), or providing a confidence assessment that their answer is correct (overestimation). People's confidence is usually only weakly related to accuracy. Other research has assessed overconfidence in students' rating their academic performance; workers' assessment of workplace performance; managers' view of their managerial skills; or nurses', physicians', and medical residents' assessment of their skills and knowledge. This research has also found that actual skill and knowledge falls significantly below self-assessment of skills and knowledge. Research on deception detection has assessed judges' confidence in their detection skill compared to their actual accuracy in detecting deception and found that people are generally overconfident.

Overconfidence has several hypothesized causes. One cause is that people lack the knowledge necessary for accurate self-assessment of performance. If someone lacks the knowledge to perform well on a test or if someone is using cues that lack predictive utility on a deception detection task, he or she would also lack the

knowledge to accurately assess their poor performance, something researchers have termed the “double curse of incompetence.” For example, novice card players are less able to distinguish good from bad moves. Another cause is that people have little insight into errors of omission and cannot adjust their confidence accordingly. People over-rely on available evidence and fail to consider evidence or cues that they have missed in their judgment. For example, people may over-rely on only a few cues to deception and ignore valid cues. Further, for some topics or traits, competence is ill-defined, relative, and ambiguous, so that different people could judge competence and knowledge based on different criteria and choose those criteria by which they are more successful. People are often motivated to maintain flattering assessments of themselves and cherry-pick criteria and feedback that portrays them as the most capable and affable.

Some research has found that on easy tasks in which success is expected or on tasks in which individuals are highly skilled, people are actually underconfident. A theory of confidence of regressive estimates helps explain conflicting findings. According to this theory, when people have imperfect self-knowledge about their performance on a task, their estimate of performance is regressive toward the middle of a distribution of scores. Therefore, for difficult tasks people will overestimate their performance upward and display overconfidence, but on easy tasks people will underestimate their performance downward and display underconfidence.

Detecting deception is especially prone to overconfidence because it is a very difficult task in which people generally perform only slightly better than chance. Further, because there are many cues that people can use to detect truth and deception, people tend to over-rely on a small subset of cues that may or may not have any predictive utility, and they then fail to consider cues they have omitted from consideration.

Overconfidence can result in many negative outcomes. Research in the field of health has found that people who are unrealistically optimistic and confident about their health and future outcomes are less likely to take measures to minimize health risks (such as using seat belts or condoms). Overconfident students overestimate their level of

comprehension after reading a text, and as the “double curse of incompetence” would suggest, the poorest students are often the least calibrated about their comprehension of material. Research into the effects of overconfidence on chief executive officers (CEOs) found that predictors of CEO overconfidence (media praise, past success, high power in comparison to other executives) were related to poor stock performance.

Overconfidence has been implicated in many famous decision failures. For example, during the 1996 ill-fated Mount Everest expedition detailed in Jon Krakauer’s *Into Thin Air* (1999), the expedition leaders minimized the risks of climbing Mount Everest, recklessly violated their own safety rules, and failed to prepare for potential obstacles and setbacks caused by a storm. The 2009 British Petroleum (BP) oil spill into the Gulf of Mexico was preceded by minimization of potential hazards and negligence of safety standards by overconfident BP executives.

Overconfidence can be beneficial. Overconfident entrepreneurs work harder during the initial start of their business. Overconfident advisors are more likely to have their advice accepted. Overconfidence can also contribute to positive self-esteem.

There are many solutions to combatting overconfidence. One solution for student overconfidence is to expose students to especially difficult scenarios or obstacles that can reveal gaps in their knowledge and skills. Research in the workplace has stressed the importance of rating systems and providing feedback, especially from outsiders not involved in the project. For repeated decisions, procedures and routines can be put in place that help combat the destructive effects of individual overconfidence.

The study of overconfidence is part of a larger body of research on positivity illusions that has found that people generally perceive themselves and their future prospects more optimistically and positively than may be reasonable by statistical chance or reality.

## Paltering

A lie involves three components: intent, literal meaning, and effect. A liar (1) presents factually incorrect information with the intent to deceive, (2) communicates information that is literally untrue, and (3) produces the effect of having the listener believe that the false information is true. Conversely, if these three components are missing in a communication, the statement would be considered truthful.

Many communications, however, fall somewhere between outright lying and truth-telling. In these communications, an element of full-blown lying is missing, as is an element of truth-telling. For example, if the intent component of a lie is missing, the speaker would be communicating a false statement he or she believes to be true. While such communications may be viewed as reckless or negligent (for example, former president George W. Bush's claim of Saddam Hussein's nuclear arsenal), because they lack the element of intent they would likely not be viewed as lying or fraudulent. Within a legal context, when intent to deceive is absent, lying or fraud is missing as well.

In another set of communications, the first and third components of lying (that is, intent and achieved deception) are present, while the second component (that is, the literal untruth of the communication) is relaxed. These communications

bend, stretch, shade, slant, and distort the truth. However, they manage to fall short of outright lying. These insincere, misleading, and deceptive communications have been referred to as "palters," and their use has been called "paltering."

The goal of the palterer and the liar is exactly the same: to mislead or deceive the listener. However, the palterer's communication, unlike that of the liar, falls short of a literal falsehood or untruth. The palterer's message typically contains a "grain of truth," which keeps it short of a full-blown lie. For example, an aspiring actress was hired as an extra in a crowd scene of a major motion picture. Subsequently, she posted on her resume that she had acted in this movie with Robert DeNiro, the film's star. While her statement was not a total lie, it was clearly deceptive and designed to exaggerate her acting prominence and perhaps entice other filmmakers to offer her roles.

A former musician tells his friends that he played drums with the famous Tommy Dorsey orchestra and turned down an opportunity to tour with the renowned rock group, Rare Earth. In reality, he sat in with the orchestra for one number while the group's drummer relieved himself, and he was asked to tour with the Sunliners, who years later changed their name to Rare Earth.

There are several varieties of paltering based on what the palterer says or does, or neglects to say or do. Perhaps the most common and least

consequential form is the social or “white palter,” often employed as etiquette or tact. Examples include telling an overweight person their outfits make them look slim, making up a prior commitment to avoid an undesirable social event, and the memorable *Seinfeld* episode in which Jerry and George, after observing a homely infant, exclaim, “Now, that’s a baby!”

*President Bill Clinton kisses First Lady Hillary Clinton in the White House, December 18, 1997. When the story of his earlier affair with Monica Lewinsky broke just one month later, Clinton paltered to the press, stating—with a critical pause—“I did not have sexual relations with that woman . . . Miss Lewinsky.”*

Another form of paltering occurs when people take advantage of the misimpressions of others. For example, an author, a Ph.D., hoping to receive more prompt and professional medical care, failed to correct the misperception of hospital staff that he was an M.D. Other palterers use vague or ambiguous terms to misguide others. For example, the marquis of an Italian restaurant proclaimed, “Voted best on the beach 15 years!” Of course, who voted, best what, and which 15-year period were not specified.

Another variety of paltering involves deliberate actions intended to mislead or deceive others. For example, college professors have been known to make hotel and restaurant reservations as “Dr. So-and-So,” hoping to be seen as more important and affluent than underpaid academics. Some businesses and home owners place surveillance warning stickers around their property, yet have no security cameras or alarm systems on their premises. Around tax time, the Internal Revenue Service (IRS) sends out press releases, which suggest a highly exaggerated probability of being audited. Other examples include litigation attorneys who mislead juries by discrediting truthful witnesses and the mudslinging campaigns of politicians against their rivals.

While paltering can be as destructive and as costly as outright lying, liars often prefer paltering for several reasons. First, compared to lying, paltering appears less deceptive, and palterers are typically seen as less responsible for their actions. Even if the palterer’s deception is discerned, the recipient is usually reluctant to call the palterer “a dirty liar.” Second, harsh legal and nonlegal social sanctions are rarely applied to paltering. Third, while there may be only one or a few ways to lie, there are often several creative ways to palter. Fourth, there appears to be less guilt and shame associated with paltering than lying. Finally, when palterers are discovered, they can claim to be misunderstood. Compared to liars, palterers have more “wiggle room” in which to defend or justify their statements and actions and escape full blame and responsibility.

Recall, for example, former president Bill Clinton’s infamous proclamation in 1998, “I did not have sexual relations with that woman.” Most agree this statement was designed to mislead the public and the Congress, not to mention his wife

and family. When Clinton's palter was uncovered, however, he attempted to neutralize his guilt by claiming "oral sex" and "sexual relations" were separate and distinct categories. The response to Clinton's palter, while inconvenient and damaging to his reputation, paled in comparison to the sanction for Richard Nixon's outright lie in 1973, "I am not a crook."

Which is worse, lying or paltering? Both the liar and the palterer intend to misguide or deceive others, and both frequently achieve this outcome. The sole difference between these deceivers is that the palterer's falsehood is disguised, obscured, and less literal than that of the liar. Thus, compared with lying, the deception and harm caused by paltering are harder to distinguish and prove. Also, victims of paltering typically blame themselves for being deceived or "taken in" by the palterer and often feel embarrassed for falling for a palterer's clever deception (for example, Orson Welles's *War of the Worlds* radio spoof in 1938). Victims of outright lies, on the other hand, are more likely to be enraged, to fully blame the liar, and to want revenge or compensation (for example, Bernie Madoff's Ponzi scheme in 2008).

Some have argued that palters (taken in aggregate) are more common than outright lies, cause as much harm as lies, and therefore should be subjected to the same legal and nonlegal social sanctions as lying. Some evidence suggests this is slowly beginning to happen. For example, certain tax, securities, and real estate statutes now sanction various omissions, misrepresentations, and evasions. Overall, however, laws as well as harsh social sanctions remain little used deterrents against paltering.

## Park, Hee Sun

Hee Sun Park is on the faculty of the Media School at Korea University in Seoul, South Korea. She has propounded a number of highly influential ideas related to deception and deception detection, including the veracity effect, the Park-Levine probability model, and ideas regarding how people really detect lies. Her research on deception, in collaboration with Timothy R. Levine, has been funded by the U.S. Department of Defense, the U.S. Department of Justice, and the National Science Foundation. Besides deception, her research focuses on cross-cultural communication, especially the use of apologies and "thank yous."

Park was born in 1971 in Seoul, South Korea. At age 21 she came to the United States to study English, where she discovered the academic field of human communication. She earned her B.A. from Michigan State University, her master's degree from University of Hawai'i, and her Ph.D. from the University of California, Santa Barbara, in 2003. From 2002 to 2013 she was on the faculty at Michigan State University in the Department of Communication. In 2008, she received the prestigious Young Scholar Award from the International Communication Association, and in 2009 she received the Early Career Award from the International Academy of Intercultural Research. In 2013, she was an associate editor of the *International Journal of Intercultural Relations*. She is a prolific researcher, having published more than 80 articles in academic journals.

### Veracity Effect

Hee Sun Park's most influential contribution to deception research was her 1999 paper describing the "veracity effect," which is the idea that

because people are typically truth biased, they tend to get truths right more often than lies in deception detection experiments. She developed the idea while taking a class on deception as a graduate student.

Prior to the publication of the paper on the veracity effect, most research looking at deception detection accuracy averaged across truths and lies when calculating accuracy. This research found that people are typically slightly better than chance at distinguishing between truths and lies. The average accuracy in such research is just under 54 percent. That research also found that people are usually truth biased; that is, people guess truths more often than they guess lies.

Park reasoned that because people are more likely to believe than disbelieve (that is, they are truth biased), they would be right about truths more often than about lies. People would be much better than 50/50 recognizing honest messages and below 50/50 recognizing lies. Consequently, the conclusion that people were 54 percent accurate at deception detection was potentially misleading. A more careful conclusion required looking at accuracy for truths and lies separately.

In 1999, teaming up with Timothy R. Levine and Steven McCornack, Park published the findings in a series of four experiments documenting the veracity effect in *Communication Monographs*. Accuracy for truths ranged from 75 percent to 82 percent, while accuracy for lies fell between 31 percent and 39 percent. How often people made correct truth-lie judgments was impacted by the veracity of the message they judged. People most often correctly believed truthful messages, while incorrectly believing lies. Following the publication of the veracity effect study, it has become more common for research to report accuracy for truths and lies separately.

An implication of the veracity effect is that the truth-lie base rate should influence deception detection accuracy. The findings that people are 54 percent accurate at distinguishing truths from lies not only involves averaging across truths and lies but also people judging an equal number of truths and lies. The truth-lie base rate refers to the proportion of messages that are truthful compared to how many are lies in a deception detection task. The logic of the veracity effect predicts that as the proportion of messages

judged becomes increasingly honest, accuracy will increase. In contrast, the more the base rate becomes tilted toward more lies than truths, the lower the accuracy.

Park devised the Park-Levine Probability Model to predict precisely how the truth-lie base rate should influence deception detection accuracy. She came up with the idea while taking a math class during her Ph.D. education and published it in *Communication Monographs* with Timothy R. Levine in 2001. Predicted accuracy is specified by the model to be the product of truth accuracy and the proportion of messages that are true, plus the product of accuracy for lies and the proportion of messages that are lies. This formula predicts a linear relationship between the proportion of messages that are honest and the accuracy with which truths and lies are distinguished. Subsequent research showed that the Park-Levine model predicts the outcomes of deception detection experiments very well.

### **“How People Really Detect Lies”**

Park’s other highly influential idea relates to “How People Really Detect Lies,” a paper she and her colleagues published in 2002. Most social scientific theories of deception are based on the ideas that liars behave differently from honest people, that people detect lies by observing others’ nonverbal behaviors, and that careful attention to the right nonverbal behaviors provides a useful way to detect deception. In almost all deception detection experiments, research subjects are asked to make truth-lie judgments shortly after hearing each potential deceptive message and to do so based on a potential liar’s verbal and nonverbal behaviors.

Park doubted that this is how people detect lies outside the research lab. To make her point, she and her colleagues conducted a very simple research study. Two hundred research subjects were surveyed and asked about a recent situation in which they had discovered a lie. Participants who could recall discovering a lie were asked to describe how it was that they found out that they had been lied to.

The results were striking. As Park had expected, most lies were not detected through the observation of sender nonverbal behavior, and most lies were discovered well after the time the lie was told. Instead, most lies were detected either because the

liar later confessed to lying or because the lie was contradicted by some evidence. Common types of evidence included information from other people, prior knowledge, and physical evidence.

The implications of these findings are that the lie detection tasks performed in deception detection experiments are different in many important ways from how people detect deception outside the lab. In the lab, liars do not confess and verbal content is of less use because statements cannot be fact-checked. In nonresearch deception detection, in contrast, people try to persuade people to tell them the truth, and they use a variety of types of evidence that are not available in the typical experiment.

## Park-Levine Probability Model

The Park-Levine Probability Model is a formula showing how deception detection accuracy varies

as a linear function of the truth-lie base rate. The truth-lie base rate has to do with the percentages of truths and lies being judged in a deception detection task, and accuracy is the percent of correct truth-lie discriminations in a deception detection task. Truth bias is also an important consideration. Truth bias refers to the tendency to judge messages as honest regardless of their actual honesty. So long as people are truth-biased, the model predicts that as the messages under scrutiny become proportionally more honest, the accuracy of the judgments increases. Conversely, the model shows that the greater the proportion of lies, the lower the resulting accuracy. If the extent of truth bias and the accuracy for truths and lies are known for one specific base rate, for example 50 percent truths and 50 percent lies, the model can be used to determine what the accuracy would be at a different base rate, for example with 75 percent lies and 25 percent truths.

Specifically, the model predicts that the percentage of accuracy with which truths and lies are correctly discriminated will equal the accuracy for only truths, times the proportion of messages that are truthful, plus the accuracy for lies, times the proportion of messages that are lies. That is,  $\text{accuracy} = (\text{truth accuracy})(\text{truth proportion}) + (\text{lie accuracy})(\text{lie proportion})$ .

As an example, imagine that the overall observed accuracy in a deception detection experiment, in which judges were shown 10 truths and 10 lies, was 55 percent correct. Imagine further that the judges were truth biased and more accurate for truths than lies, getting 75 percent of the truths correct but only 35 percent of the lies right. Because there are an equal number of truths and lies, the truth-lie base rate and the proportion of truths and lies are all 0.50. So, there is an accuracy of  $0.55 = (0.75)(0.50) + (0.35)(0.50)$ .

If the base rate was 90 percent truths and 10 percent lies, the model predicts that accuracy would increase to  $(0.75)(0.90) + (0.35)(0.10) = 0.71$ , or 71 percent. In contrast, if the base rate were 90 percent lies and 10 percent truths, the model holds that accuracy would fall to  $(0.75)(0.10) + (0.35)(0.90) = 0.39$ , or 39 percent accuracy. If 0.71, 0.55, and 0.39 were plotted, each accuracy figure would fall on a straight line.

The model predicts a linear relationship between the proportion of messages that are

honest and deception detection accuracy. The slope of the linear relationship is a function of truth bias. The slope becomes steeper as truth-bias increases. Consequently, the truth-lie base rate makes a bigger difference when truth biases are strong. If judges were lie-biased, the slope would be negative.

Research has strongly supported the utility and predictive power of the Park-Levine model. In a paper published in 1999, Levine and his colleagues showed that people are generally truth-biased, and that accuracy increased linearly as the base rate increased from 75 percent lies to 75 percent truths.

In another study published in 2006, Levine and his colleagues offered a more precise test of the model. Truth and lie accuracies were measured in a control group with 50 percent truths and 50 percent lies. Then an experiment exposed judges to deception detection tasks with a variety of several different base rates ranging from all lies to all truths. Accuracies were observed in the experimental groups and compared to accuracies predicted by the model, using the base rate and the accuracies from the control group. The experiment showed that the Park-Levine-model predictions closely approximated the experimental results. The predicted linear relationship was observed, and all accuracies were predicted to within 2 percentage points. The model has also been supported by several experiments that are as yet unpublished.

The most controversial feature of the model rests on its probabilistic nature. Like most basic probability calculations, it presumes that probabilities are constant over observations and that people are insensitive to base rates. This makes the Park-Levine Probability Model at odds with theories of deception detection that predict that people are sensitive to others' actual honesty and that accuracy is dynamic over time.

The model has important real-world applications. The likelihood of encountering deception changes from situation to situation and person to person. Talking to a close and trusted friend is different from talking to an aggressive salesperson. Listening to the promises of a politician seeking reelection is different from listening to the advice of the family physician. Base rates are not constant, and an equal number of truths and lies occur only inside the research lab. The

Park-Levine Probability Model is useful in showing how deception detection changes from situation to situation.

Lie detection is especially challenging in situations in which lies occur at a low base rate. An example might be catching terrorists boarding airplanes. Because most passengers are not terrorists, most people who are suspected are likely to be innocent. Most people claiming a lack of terroristic intent will be honest. Picking out the few who are not is probabilistically a challenge. So, even though accuracy as a percentage will be high in a low base-rate situation (that is, most people are correctly not suspected of being terrorists), the chances of correctly identifying the isolated liar may be poor.

For researchers, the model is useful because most deception detection experiments employ only one base rate, usually 50/50 truths-lies. If subjects are truth biased, as is typical, the results only apply to the specific base rate. The Park-Levine Probability Model allows researchers to estimate how different base rates might affect the results.

Because people are most often truth biased, because more people tend to be more honest than not, and because most experiments use a 50/50 base rate, the Park-Levine model shows that most deception detection experiments may provide an overly pessimistic view of deception detection accuracy. The 54 percent accuracy finding in the research involves studies using a 50/50 base rate. But, most people do not lie half of the time. So, truth bias may be functional, and experimentally imposed base/rates may be unrealistic. On the other hand, in environments in which lies are highly likely, accuracy may dip below 50 percent

## Pathological Lying

Pathological lying, also known as *mythomania* or *pseudologia fantastica*, is an illness or behavior characterized by compulsive or habitual lying. One of the most widely accepted definitions of pathological lying was written in 1915, by W. Healy and M. T. Healy, two psychologists who first attempted to define the disorder and who brought pathological lying to the public eye. They describe pathological lying as having four criteria. First, pathological liars often have no discernible motive or reason to lie. Second, the lying is typically complicated, interwoven into a web of lies with multiple layers. Third, the lying can take place over a long period and usually encompasses several years of extensive lying. And fourth, pathological lying cannot be merely a symptom of another disorder.

Healy and Healy based their conceptualization of pathological liars on patients they encountered, and it is useful to consider one of these patients in the context of this conceptualization of pathological liars. Patient Janet B. was a 19-year-old female and presented all four components. Janet's lying was described as consisting of lies that had no clear reason, including lying about the existence of a man who had saved her life as a child, her purchase of an exorbitantly expensive sewing machine, and her constant reference to various medical illnesses and nervous disorders from which she claimed to suffered.

Janet's lies were incredibly complicated and multifaceted, presented as stories rather than single untruths. She claimed to have a relationship with a man who did not exist, whom she met in a western town where she has never visited, and who died in an accident that never occurred. Janet's parents were able to verify the major falsehoods.

This ground truth is critical in the study of pathological liars because without ground truth it is difficult to diagnose the magnitude of the deception.

To be considered pathological, the lying behaviors must be both long-term and regular, and not simply a reaction to a single event. In Janet's case, her excessive lying began at the age of 12 or 13 and lasted over six years. This duration of deceptive behavior is an important and distinguishing characteristic of pathological lying, although the scientific community has not agreed upon a specific time frame.

### Pathological Lying and Related Disorders

The last requirement, the absence of other disorders, is the most controversial of this conceptualization of pathological liars. If pathological lying is observed in a person with no other known mental disorders, then pathological lying can be classified as a disorder on its own. If individuals with other diseases, such as insanity or malingering, display pathological lying then pathological lying should be perceived as only a symptom of another disorder. Janet B. exemplifies the conception of a pathological liar because she displayed no other signs of mental or physical illnesses.

There are at least two disorders in which pathological lying may reasonably be thought of as a symptom. These two disorders are factitious disorder and borderline personality disorder. Factitious disorder is the intentional production of contrived symptoms for maintaining the role and appearance of a sick person. Borderline personality disorder is often characterized by pathological lying because the individual lies to form new versions of his or her own self-identity. The reason that these two disorders do not independently qualify as pathological lying is that, in the first example, there is a goal of being seen as an invalid. In the example of borderline personality disorder, the individual does not have a clear perception of who he is, so his intention to mislead is not sufficient to qualify as deceptive. Therefore, though factitious disorder and borderline personality disorder may have similar characteristics to pathological lying, they do not overlap, because of the difference in the intentions of the individual.

Besides the case of Janet, other individuals provide evidence that pathological lying is an independent disorder. Pathological lying can be

identified among successful and accomplished individuals who do not have another apparent mental disorder or a history of criminal behavior. For instance, the State of California Commission on Judicial Performance dismissed Judge Patrick Couwenberg because Couwenberg had told numerous lies about his accomplishments, many of which were responsible for earning him his prestigious position. The judge, who was ruled fit in all other capacities except his inability to stop his misrepresentations, had lied about having a master's degree in psychology, serving in Vietnam, as well as many other deceptions, all of which proved to be untrue. The Couwenberg case indicates that even materially successful people may be overcome by a need to lie for no apparent reason.

### Neurological Traits of Pathological Lying

Though people like Janet B. and Judge Couwenberg exist in society, most people are intrinsically truthful. People have a tendency to judge messages as truthful rather than deceptive, independent of whether the statement is true or not, a phenomenon known as the truth bias. Communication would fail if everyone believed that they were always being lied to. It is possible, therefore, that pathological liars may be neurologically different from other people. An examination of the structure of the brain using magnetic resonance imagery (MRI) revealed an important difference between the brains of people deemed to be pathological liars and the brains of "normal" controls.

The individuals who were identified as pathological liars showed an increase in prefrontal white matter compared with controls. White matter is the portion of the brain that consists of axons that provide the mechanism for neural activity. The link between prefrontal white matter and increased capability for deception is the increased cognitive capacity associated with white matter. Though this increased capability to lie does not imply causation, it does signal a relationship between the increased neural activity and increased likelihood of lying.

The link between increased white matter and deception is also supported by the study of the cognitive development of children. Young children from the ages of 3 to 8 are particularly inept at lying or telling any type of falsehood, yet by the time they reach the age of 10 they have become

adept at deception. This increase in the ability to deceive coincides with the human brain reaching adult weight and a marked increase in the absolute volume of white matter.

### Do Pathological Liars Know They Lie?

Perhaps the obvious question one must ask when examining pathological lying is whether or not the patient knows that he is lying. The general consensus is yes, but there are complications. For a pathological liar to have no idea that her statements are false, and to lie to the extent that she does, the patient would have to be completely delusional. Generally, when pathological liars are trapped in a corner and confronted about a lie, they will admit to having exaggerated or been mistaken. However, by this concession they only admitted to lying about one small detail in their web of lies. Psychologists have come to believe that although pathological liars are not delusional and do not truly believe individual lies, they come to accept and believe the overall narratives and personas they have fabricated about themselves.

For people who display symptoms of pathological lying, no panacea exists. Instead, the most recommended line of treatment is psychotherapy. Psychotherapy sessions for pathological liars are usually long term and complex. Often, the goal of the psychotherapy sessions is to weed out the root of the problem by asking the patient to illustrate certain portions of his past. In the case of Janet B., the psychologists were able to ascertain that early sexual experiences coincided with the beginning of her pathological lying. The troubling issue of psychotherapy as a treatment for pathological lying is that there is no verification that what the patient tells the therapist is not just another lie. However, to date, there is no pharmacological treatment for pathological lying, and psychotherapy is believed to be the best approach.

Although the definition of pathological lying may be contested, the rarity of pathological liars is relatively undisputed. In a study examining 1,000 repeat juvenile offenders, less than 1 percent were identified as possible pathological liars. Yet perhaps what fascinates the public about pathological lying, and is responsible for the numerous movies and books on the subject, is what fascinates people with lying in general: pathological liars break the rules that tell individuals to tell

the truth, but they break this rule over and over again, for no apparent reason.

## Perjury

When someone commits an act of deception while under oath in a legal proceeding, that person can be charged with the crime of perjury. The classification of crime and resulting punishment varies by jurisdiction, but it is usually a felony that carries a fine, a prison sentence, or both. A person may commit perjury in an attempt to protect either himself or someone else or, in the case of a law enforcement official, may be motivated by the desire to secure a conviction. Despite a widespread belief that perjury is common, the crime is difficult to prove because of the strict requirements of evidence, and it is relatively easy to

defend based on such claims as forgetfulness. As a result, only very strong cases tend to be prosecuted, so although there are few cases overall, there is a high rate of conviction.

In early societies, such as the Roman Empire, lying under oath had both moral and religious implications and was treated as a sin rather than a crime. The modern origin of the crime can be traced back to 16th-century England, when the Perjury Statute of 1563 was enacted, making perjury a prosecutable offense. It became part of British common law, a set of legal precedents that are used to decide court cases. The U.S. legal system, including its perjury laws, is based on British common law.

There are two main sections of U.S. law, Chapter 79, Title 18, Sections 1621 and 1623, which contain definitions of perjury. According to these laws, a deceptive statement must contain a number of elements to qualify as perjury. First, as with most definitions of deception, the false statement must be made knowingly with the intent to mislead. This eliminates cases in which the witness made a false statement because of a bad memory or because he was confused by the question. Second, the statement must be unambiguously false. A statement that is misleading, but technically true, is not perjury. Third, the statement must be material. This means that it must be of some importance and have a direct influence on the potential outcome of the related proceeding. A lie that is minor or unrelated to the case would not qualify as perjury.

Fourth, the statement must be made after the witness has sworn under oath to tell the truth. A witness who lies to a police officer has not committed perjury because she is not under oath. Finally, the witness must make the statement either as part of a judicial proceeding or after acknowledging that she is operating under penalty of perjury. This includes written and oral statements in both civil and criminal courtroom proceedings, sworn depositions taken outside of the courtroom, testimonies before legislative bodies, and statements such as income tax returns, which are signed under penalty of perjury. A federal perjury conviction carries a maximum of five years in prison, with a maximum fine of between \$2,000 and \$10,000, depending on the exact charge.

Individual U.S. states and other countries have laws that apply to their own judicial systems; these may be somewhat different from the U.S. laws. For example, New York State Penal Code Article 210 defines three degrees of perjury, ranging in severity from a class A misdemeanor, punishable by up to one year in jail, to a class D felony, punishable by up to seven years in state prison. In Michigan, someone who commits perjury in a capital felony case can receive a life sentence. Canada has a maximum penalty of 14 years in prison. On the opposite end of the spectrum is France, where criminal suspects cannot technically commit perjury because they are not allowed to testify under oath.

There are a number of reasons someone might lie while under oath. The self-interested criminal defendant may perjure himself in an attempt to escape a conviction. A witness may lie under oath in order to protect a friend or family member. For example, the sister of an accused criminal might testify that the defendant was home in bed at the time the crime occurred, when in fact she did not see her brother that night and does not know where he was. Law enforcement officials may testify falsely or even manufacture evidence against a defendant to help obtain a conviction. In a study done on New York City police officers in 2000, more than 75 percent admitted they would be likely to commit perjury in a variety of hypothetical situations. Most of the officers felt they would be morally justified in lying under oath if it meant helping secure a conviction against someone they strongly believed to be guilty.

### **Prosecuting Perjury**

Despite the belief that perjury is common, statistics indicate that prosecutions are rare. Many of the cases that do reach trial, however, result in a conviction. According to U.S. Department of Justice statistics, only 237 cases in the category “perjury, contempt, and intimidation” were tried in federal courts during a 12-month period in 2003–04. This was 0.27 percent of all federal cases tried during that time period. However, almost 80 percent of those cases resulted in conviction.

One reason perjury is not often prosecuted is that proving perjury in a court of law is very difficult because of the standards of evidence that must be met. The prosecution must prove beyond

doubt that the deceptive statement meets all the legal requirements for perjury. In most jurisdictions, prosecutors must also produce at least two independent witnesses to contradict the statement in question or one witness plus additional evidence that the statement was false. If they cannot find two witnesses or additional evidence, perjury can be proved on the basis of the witness himself making two contradictory statements. The prosecution does not have to prove which of the statements was false, just that they were mutually exclusive and met the other qualifying criteria.

Other reasons a perjury charge might not be pursued are related to the type of legal case involved. In civil cases, the government may avoid filing a perjury charge because of the expense relative to the small number of people affected by the outcome of the case. In criminal cases, many of the alleged perjurers have already been convicted of the more serious crime of which they were accused, and the time and expense involved in prosecuting them for the additional perjury offense would not be worthwhile.

There are also many tactics for defending against a perjury charge, so prosecutors are unlikely to pursue a case unless they are confident of success. One common defense strategy is recantation, meaning that the witness testifies to knowingly making a false statement and withdraws that statement. The new testimony must contain a clear admission that the statement was false, and cannot be presented as a request to clarify or provide additional information. If the recantation is done before the case reaches a conclusion (for example, before the jury begins deliberations), and the witness had no reason to believe that his lie was about to be exposed, the prosecution is unlikely to file perjury charges.

Less complicated defense strategies include claims of forgetfulness, of not fully understanding the question, or the “literal truth” defense: acknowledging that the testimony may have been misleading, but it was technically true. It can be very difficult for the prosecution to counteract these defenses and prove that the accused perjurer knew that she was making a false statement.

### **Well-Known Perjury Cases**

A closer examination of famous perjury cases helps illustrate how rigorous the proof of the

*Secretary of State Edward R. Stettinius (left) and Alger Hiss of the U.S. State Department (second from left) at the Yalta Conference in Yalta, Soviet Crimea, January 1945. Hiss, a member of the U.S. delegation headed by Stettinius, ostensibly met to coordinate strategy to defeat the Nazis. However, by 1950, Hiss was convicted of perjury by lying to the House Un-American Activities Committee about his affiliation with the Communist Party, allegations backed up by espionage documents provided by communist Whittaker Chambers.*

crime must be. Two well-known cases that resulted in conviction were the case against Detective Mark Fuhrman, a police officer who testified in the 1995 O. J. Simpson murder trial, and the case against Alger Hiss, who was convicted based on testimony he gave when he was on trial for espionage.

During the Simpson trial, Fuhrman testified that he had not used a particular racial slur at any point in the previous 10 years. The prosecution had several witnesses who refuted this statement, plus audio tape of the defendant using the term repeatedly. The trial did not reach the stage of jury deliberations. Faced with the strong evidence against him, Fuhrman made a plea agreement in which he received three years felony probation in lieu of jail time.

The case against Hiss, a former State Department official, resulted in one of the most widely publicized perjury trials in U.S. history. In 1950,

Hiss was convicted of lying to the House Un-American Activities Committee about his affiliation with the Communist Party; specifically, he denied knowing a man named Whittaker Chambers, who had already testified that he was well acquainted with Hiss through the Communist Party. As part of the investigation, Chambers turned over documents that appeared to have originated from Hiss. These documents implicated Hiss as part of an espionage plot with the Soviets. However, because the statute of limitations for the espionage charge had passed, the government chose to prosecute Hiss for perjury. Hiss had two separate perjury trials; the first ended in a mistrial, and the second in a conviction. He was sentenced to the maximum term of five years in federal prison, but he claimed innocence until his death.

It is also instructive to look at famous perjury cases in which the accused party was not

convicted to see how cases can be defended. Two recent well-known cases involved President Bill Clinton and professional baseball player Roger Clemens. In Clinton's case, the perjury allegations were part of independent counsel Kenneth Starr's 1998 report to Congress regarding Clinton's potential impeachment. The report said that Clinton lied under oath when testifying to a grand jury about his relationship with then-White House intern Monica Lewinsky, denying that they had a sexual relationship. Clinton used the literal truth defense, claiming that the way the questions were worded, he had indeed answered truthfully. The perjury charge was eventually rejected by the Senate.

Former Major League baseball pitcher Clemens was charged with perjury for allegedly lying to Congress in 2008 when he testified that he had never used steroids or human growth hormones during his professional career. The case centered on trainer Brian McNamee's claim that he had personally injected Clemens with the drugs. Because prosecutors had only a single contradictory witness, they needed independent evidence that Clemens had knowingly testified falsely, and they were unable to produce this. Clemens's 2011 trial ended in a mistrial, and in 2012, the jury in a second trial acquitted him of the charges.

### Conclusion

An individual can be charged with perjury if he knowingly makes a material false statement while under oath in a legal context. Perjury is a felony under U.S. law, although there can be other classifications at the state level based on the circumstances of the case. Punishment typically involves a prison sentence, a fine, or both. Motives for committing perjury include self-interest, protecting another person and, in the case of law enforcement officials, helping obtain a conviction. Based on available statistics, it appears that perjury is rarely prosecuted, but a large percentage of prosecuted cases result in conviction. Because of the difficulty in proving that a defendant intended to lie under oath, the prosecution must be confident of its case before pursuing it. Looking more closely at examples of famous perjury cases, such as Mark Fuhrman's conviction or former president Clinton's acquittal, helps

illustrate the burden the prosecution faces when trying to prove perjury.

## Photographs, Altered

Altered photographs have been manipulated, either digitally or manually, in order to change the content of the photographic image. The alteration of photographs has occurred since shortly after

the invention of the permanent photograph in the early 19th century, although its prevalence has increased with the advent of photo manipulation software. An altered, or “doctored,” photograph can be a particularly insidious means of deception because people tend to perceive photographs as highly credible, accurate representations of people and events. The very existence of a photograph of an event, then, can be taken as evidence that the event truly occurred. Photographs are often used as proof that an event occurred, both in the media and in legal settings. Photographs are doctored for many reasons, ranging from achieving political gain to altering one’s physical appearance to editing out minor background details in order to improve the photographic composition. Research on altered photographs has suggested that viewing doctored images can influence peoples’ preferences, attitudes, and even memories of past events.

Photographs have been manipulated since at least 1840. Before the use of computers made photo alteration widespread and easily accessible, alteration techniques involved manipulating the film or prints. Among the more crude methods were painting the print or retouching the negative. Other techniques were more subtle: double exposure involved exposing the film twice to incorporate components of two scenes into the same image, while combination printing involved using two or more negatives to create a single print. Early photographic alteration was done not to mislead viewers but to improve the accuracy of the image, as photographers were frustrated by the technology’s limitations in its depiction of color and lighting.

Altered photographs have been used to deceive viewers for political reasons as early as 1871, when Ernest Eugene Appert doctored photographs of the Paris Commune massacres as propaganda for the Versailles government. Later, many examples originated in the years just prior to World War II. Stalin, Hitler, and Mao Zedong all had photographs of themselves altered by removing high-ranking political rivals (e.g., Trotsky, Goebbels, and Po Ku, respectively) in order to appear as more monolithic leaders. While the practice of altering photographs to influence public attitudes was often found in totalitarian prewar states, it is still used in contemporary politics. For example,

during the 2004 American presidential campaign, in an attempt to portray candidate John Kerry as unpatriotic, a photograph was circulated of Kerry on stage with actress Jane Fonda (who was known for her leftist political leanings) at a rally to protest the Vietnam War. However, Kerry had never attended a rally with Fonda, and it was later discovered that the photograph was a composite of two separate images. In each of these cases, the altered photographs were intended to change perceptions of—and attitudes toward—political leaders and events.

### **Influence of Altered Images**

A growing body of research has begun to investigate just how much influence over people doctored images might hold. Research investigating the effects of altered photographs often involves exposing research subjects to counterfactual images and subsequently asking about their memories for related events. Experiments with doctored photographs have demonstrated that manipulating photos can change subjects’ autobiographical memories, memories for news events, and their attitudes and preferences.

Some research suggests that peoples’ preconceived attitudes can affect how they view an altered photograph. In one study, when subjects saw doctored photographs of political events that never happened, half the time they reported that they remembered the event. Furthermore, they were more likely to say that they remembered the event when it was congruent with their prior attitudes. For example, if an altered photograph reflected poorly on a Republican politician, Democrats were more likely to say that they remembered the event, and vice versa. This finding is supported by research that suggests that events are more likely to be remembered if they are easy to imagine or in line with a person’s expectations.

Research has also investigated how doctored photographs might influence viewers. If political leaders can alter photos of events in order to deceive the public about details of those events, it is important to understand the effects that these altered photographs might have. Research using famous photographs of protests has demonstrated that when people are shown a novel doctored version, they often report recognizing it,

even though they haven't seen that version before. These doctored photographs can cause people to remember events differently (e.g., more positively or negatively), and consequently affect their attitudes about the events. Moreover, doctored photographs can change how people plan to behave in the future. When subjects were shown a photograph of a peaceful protest altered to make the event appear violent, they reported that they would be less likely to participate in protests in the future. This finding suggests that doctored photographs may be able to influence behavior, in addition to memories and attitudes.

### Participating in a Lie

In addition, experiments have shown that people can be influenced by doctored photographs of themselves. Research on product preferences has suggested that when photographs are altered to show subjects using a particular brand of product, they later prefer that brand to alternatives and even express a greater likelihood of purchasing that brand. Experimenters studying false memories—memories for events that never occurred or details that are incorrect—have shown that altered photographs can even alter a person's autobiographical memories. In one study, when researchers doctored childhood photographs of subjects to depict them in scenarios that they never experienced, 50 percent of the subjects developed false memories of those scenarios. Subjects can also develop false memories from doctored video footage of themselves, even when the footage depicts events that happened only a few days earlier.

People can be deceived by altered photographs in different contexts, such as politics, advertising, and their autobiographical memories. With the advent of image editing software, altering photographs has become even more accessible and commonplace. While altered photographs carry a serious potential to influence people, the ability to create them also provides less sinister opportunities for deception. Photographers can remove extraneous details crowding their photographs; people can view younger, more slender versions of themselves; and graphic designers can craft creative advertisements. In the modern era, because of the ubiquity of altered photographs, people are becoming accustomed

to them. However, the creation of such images represents a lie.

## Piltdown Man

The Piltdown Man, one of the biggest scientific frauds of the 20th century, demonstrates that everyone, even so-called experts, can be gullible.

On December 18, 1912, Charles Dawson presented hominid bone fragments he had discovered in a gravel yard near Piltdown, East Sussex, England, to the Geological Society of London. Dawson and his partner, Arthur Smith Woodward, keeper of the geological department at the British Museum, maintained the reconstructed fragments (skull, jawbone, and teeth) indicated the Piltdown Man was most likely the missing link between apes and humans. Thus began a notorious hoax that lasted for over 40 years. Why did most scientists of the day blindly accept the fraudulent findings when more scientifically credible missing links were ignored? Who perpetrated this blatant fraud? How was the scientific community deceived for so long?

Although some (mostly American and European) scientists soon questioned Dawson's findings, they were ignored or vigorously attacked. Why? British national pride definitely played a role. How could anyone question evidence that proved what every British citizen knew in his heart: of course Britain was the origin of modern man and civilization. Moreover, scientists had a working assumption that the missing link would have evolved mentally first, thus having a human-like brain with other features remaining ape-like.

When Dawson presented bone fragments suggesting a human-like skull and an ape-like jaw, many scientists were overjoyed that their hypothesis was correct (a clear example of confirmation bias—the tendency to favor information confirming existing beliefs.) Scientists who questioned the authenticity of the Piltdown Man discoveries were silenced two years later, when Dawson conveniently found new Piltdown Man fragments just two miles away from the original site. It would be too much of a coincidence to find this combination of fragments together twice; they must belong together.

Why did it take over 40 years (and over 500 scientific essays on Piltdown Man) for someone to look for evidence of fraud? Dawson was well known in the field. Though he was an amateur archaeologist, he made many significant finds, including a previously unknown species of mammal, three new dinosaur species, and a new form of fossil plant, and several of his discoveries were named after him (*Plagiaulax dawsoni*, *Iguanodon dawsoni*, and *Salaginella dawsoni*). For these

finds, the British Museum named him an honorary collector, and he was elected a fellow of both the Geological Society of London and the Society of Antiquaries of London. Because Dawson was perceived as distinguished and reputable, he seemed a credible expert source whose findings must be correct.

It's interesting to note that in 1891, a Dutch paleoanthropologist and geologist found authentic remains in Java of an ape-man with a small brain that stood erect (*Homo erectus*.) Even though his facts were meticulously logged and documented, and he carefully verified his results, the scientific community ignored and ridiculed him. He had the misfortune to be an unknown, unconnected foreigner (of suspect credibility) who discovered something contradicting prevailing theories. (Yet another sad example of confirmation bias.)

Even in 1949, when a new flourine dating test revealed the age of the Piltdown artifacts as relatively recent rather than ancient fossils, it still didn't occur to anyone that something associated with Dawson could be a fabrication. Not until 1953, when Piltdown Man did not match with accumulating missing-link fossils discovered over the years, did someone examine the artifacts for deliberate fraud. J. S. Wiener was amazed at the strikingly clear indicators of fraud: There was obvious evidence that the teeth had been filed down. Later tests indicated that skull fragments were from medieval humans, the jawbone was from an orangutan, and the canine tooth was from a chimpanzee fossil. Bones were treated with an iron and acid solution, making them appear ancient, and the canine tooth was painted and patched with chewing gum.

Who perpetuated this flagrant fraud? Dawson must have been involved. Between 1912 and 1916, scientific challenges were remarkably answered with his new "finds," and no new discoveries occurred after his death. However, in 2003, Miles Russell identified at least 38 specimens of Dawson's antiquarian collection as clear fakes, noting that Dawson's career had been "one built upon deceit, sleight of hand, fraud and deception, the ultimate gain being international recognition."

Many believe Arthur Woodward must have been involved in the hoax, as well as a few others who tended to gloss over facts as they vigorously supported their fellow Englishmen. A trunk

found in the Natural History Museum in 1970 containing animal bones and teeth carved and stained in a manner similar to the Piltdown finds throws suspicion on yet another British scientist, Martin Hinton.

But perhaps the most amusing theory has Sir Arthur Conan Doyle (of Sherlock Holmes fame) as a possible instigator. Evidently Conan Doyle lived very close to the Piltdown site and participated in some of the digs. Some speculate that Conan Doyle had a grudge against the scientific community for persecuting and discrediting a favorite psychic, so he filled the gravel yards with fake artifacts to make scientists look ridiculous. If so, he waited 40 years for satisfaction.

Whoever the perpetrators, the surprisingly long life of the hoax is the true lesson, for it reveals how people's biases and motivations can lead anyone to deceive themselves. Individuals often uncritically accept something supporting what they already believe rather than carefully evaluate all of the evidence.

## Pinocchio

Pinocchio is a character in a children's story, originally written in Italian, but later translated into English and further popularized by many movie, television, and stage adaptations, most famously the 1940 Walt Disney movie *Pinocchio*. Although more recent adaptations toned down darker

aspects of the original story, these versions have generally enhanced the message about the dangers of lying and deception and the importance of obedience.

The main character, Pinocchio, is a wooden puppet constructed by woodcarver Geppetto. Throughout the story, Pinocchio gets into a great deal of mischief both as the perpetrator and as the victim of deceit. Pinocchio's nose grows when he tells a lie, an element of the story that has made an enduring impact on popular culture. The story concludes with Pinocchio's selfless behavior, convincing a fairy to grant his wish of becoming a real boy.

*The Adventures of Pinocchio* was written in Italian by Florentine writer Carlo Lorenzini (1826–90), under the pen name of Carlo Collodi. The story was originally serialized in *Il Giornale dei Bambini*, a weekly children's newspaper. It was later published as a novel in 1883. Children's literature was a relatively new genre at the time of Collodi's writing, and the original story contains many elements that might be considered rather dark for a modern children's story. For example, Collodi initially seemed to kill Pinocchio off at the end of the story, with Pinocchio being hanged by assassins as a result of his misdeeds.

When the author was asked to continue the story, Pinocchio was rescued by the fairy with the blue hair (in Walt Disney's adaptation, the Blue Fairy), who became an important character in this portion of the story. It is in this second group of installments that a redemption theme emerges, the very theme that continues to be associated with Pinocchio today. However, in the original installments (Chapters 1 to 15 of the novel), Pinocchio is clever, disobedient, and lazy, and shows little interest in becoming "good." Only in the second installment (Chapters 16 to 36) is there some attempt to have Pinocchio's moral character develop.

In Collodi's story, the backdrop is one of chronic poverty, and death and violence seem to be constant threats. Pinocchio accidentally kills a cricket (who becomes the Jiminy Cricket character in the Disney version of the tale), and it is the ghost of the cricket who later visits Pinocchio. Pinocchio is caught in a weasel trap, and then tied to a doghouse by a farmer. He bites a cat's paw off, is turned into a donkey, and then

is sold to a man who wants to skin him. At one point, the fairy character is presented as a dying young woman.

*The Adventures of Pinocchio* was first translated into English in 1892, and there have since been additional translations. There have also been numerous movie adaptations, television broadcasts, and operas based on Collodi's novel. Some have argued that over the years, Collodi's strong-willed protagonist, who disobeys inconsistent and unjust authority figures, has, through these adaptations, changed. Instead of being actively involved and agentic in his transition from boyhood to adulthood, he has become an innocent, wide-eyed child, who eventually learns to obey his elders.

The 1940 Walt Disney musical animated movie, *Pinocchio*, was instrumental in changing Pinocchio's nature. The movie has been recognized for its breakthroughs in animation and cinematography, its musical score ("When You Wish Upon a Star" won an Oscar for Best Original Song), and its strikingly human cartoon characters. The movie, like Collodi's novel, depicts a dangerous world populated by unsavory characters. Family, however, can be trusted. Disney's Geppetto is loving and kind and had earnestly wished upon a star for a real son, whereas Collodi's Geppetto was loving but initially disliked children and was prone to anger and impatience.

In the Disney version, Pinocchio is not an active agent in creating his own destiny. He is naïve and mischievous but basically good-hearted, and he learns important lessons about truth and bravery from his experiences. Much is made of Pinocchio's nose growing when he lies, a phenomenon that was not a major plot point in Collodi's novel. The cricket character plays a larger role in the Disney version, with Jiminy Cricket agreeing to the Blue Fairy's request that he serve as Pinocchio's conscience. The Blue Fairy, rather than being the complex character of Collodi's story, who is sometimes cruel and sometimes affectionate, becomes a glamorous, sparkling, figure who can magically rescue Pinocchio.

In the Disney version, the Blue Fairy tells Pinocchio that in order to be a real boy, he must demonstrate truthfulness, bravery, and unselfishness. By the end of the story, Pinocchio proves his selflessness by giving up his own life to save Geppetto

*Pinocchio's nose grows when he lies in "Le Avventure di Pinocchio" (1902) by Carlo Collodi, illustrated by Carlo Chiostrì and A. Bongini. Originally a series in a weekly children's paper, a second group installments features a redemption theme, with the puppet being rescued by a fairy and desiring to be good.*

from a whale. The Blue Fairy recognizes Pinocchio's sacrifice and brings him back to life as a real, flesh-and-blood boy. Unlike the end of Collodi's story, in which Pinocchio is taking on adult responsibilities, the Disney version ends with Pinocchio as childlike as ever, restored to Geppetto's gentle, loving protection.

### Conclusion

The "classic" story of Pinocchio, the mischievous little puppet with which people are familiar today, is rather different from the original Italian novel. Collodi's novel drew some criticism that it encouraged disobedience, whereas the modern version has a strong lesson around the importance of obedience, truthfulness, and selflessness. Even those who know very little about Pinocchio today are likely aware that his nose grew whenever he told a

lie, a very minor component of the original story. Whereas the Pinocchio of today is a story with a strong lesson about lying, the original story was far more ambiguous in its morality.

## Plagiarism

Plagiarism refers to taking someone's ideas or words without crediting that person as the original source. Plagiarism scandals have resulted in lawsuits and the revocation of academic titles. Although estimates of the incidence of plagiarism vary widely, there are indications that plagiarism in academic settings has increased, with many blaming the Internet, large class sizes, and the commoditization of degrees for the increase. Institutions and instructors have taken steps to prevent plagiarism, for example, by modifying the structure of assignments and by promoting academic integrity in general.

In the music world, well-known artists, such as the Beach Boys, George Harrison, Michael Bolton, and the Black Eyed Peas, have been sued for copyright infringement in relation to plagiarizing the works of other songwriters. Successful book authors, such as Alex Haley (*Roots*) and Janet Dailey (author of over 100 novels), have been accused of plagiarism, with Dailey settling out of court with fellow romance novelist Nora Roberts. In journalism, Fareed Zakaria, *Newsweek* columnist, *Time* editor-at-large, and political

commentator, was accused of having used material from a fellow journalist's *New Yorker* article, and Boston Globe columnist Mike Barnicle resigned after accusations that he had plagiarized the work of author and comedian George Carlin. These plagiarism scandals highlight the importance of intellectual property rights in contemporary Western culture.

In academia, where plagiarism generally falls under the broad umbrella of academic dishonesty, the ownership of words and ideas is fiercely defended. Karl-Theodor zu Guttenberg, the German minister of defense, resigned from office after it was discovered that he had plagiarized significant portions of his doctoral dissertation. One of the most famous cases, though, was undoubtedly that of Martin Luther King, Jr., a Boston University investigation determined that the civil rights leader had plagiarized portions of his doctoral dissertation but concluded that there was not sufficient reason to posthumously revoke his doctorate.

### Plagiarism by College Undergraduates

However, aside from relatively few high-profile cases of academic misconduct by professors, concern about plagiarism has generally been focused on undergraduate students. In colleges and universities, there is a perception that student plagiarism is on the rise, and research using anonymous self-report measures of academic misconduct have generally confirmed that this is the case. In relation to plagiarism, in particular, one explanation for this perceived increase is the ease of accessing and reproducing information from Internet sources. Some authors have suggested that a generation of students who grew up downloading content from the Internet has difficulty understanding that ideas and words from the Internet have authors and are not fair game to be incorporated into one's own work.

There are several kinds of plagiarism that occur on college campuses. Some students submit essays obtained from "essay mills" or from other students, perhaps doing some minor rewording. Internet sources for essays are abundant, with students able to purchase standard or custom-written essays from these services. Students may submit the work of a friend or relative who has completed a similar assignment in the past. Another version of this form of plagiarism is self-plagiarism—submitting

the same (or a somewhat revised version of the same) essay for multiple courses, without the knowledge or permission of the instructors.

A pervasive form of plagiarism involves copying from Web sites or source texts without quotation marks and/or without citations. This plagiarism often involves copying and pasting from one or more sources, sometimes as part of the note-taking process. Sometimes these sources are cited, but the student fails to make it clear that the work remains in the original source's words or is only marginally paraphrased.

Another form of plagiarism involves collusion between two or more students on individual assignments. Students may work together and, indeed, peer collaboration is often encouraged in college classrooms. However, this same collaboration becomes highly problematic when the work of two or more students bears striking similarity, and it is sometimes unclear, even to the students, where the original ideas and words came from.

Plagiarism can be intentional or unintentional, and instructors and institutions may differ in the extent to which they consider ignorance as a mitigating factor when punishing students who plagiarize. Many cases of plagiarism are not as blatant as the purchase of an essay from a paper mill. Students might be unaware of appropriate citation standards and may genuinely believe that so long as they have moved a few words around from the source text, they have not committed plagiarism. Others have engaged in sloppy copy-and-paste note-taking and lost track of which words were their own and which came directly from source texts.

Furthermore, students and seasoned academics and professionals alike have defended their obvious plagiarism by arguing that it was entirely "accidental," professing astonishment that another's words somehow found their way into what they believed to be their own work. While there is likely some disingenuousness in many of these claims, psychologists describe "cryptomnesia" as a kind of memory bias, in which people genuinely but falsely recall that they themselves were the source of an idea or word string.

### Reasons for Plagiarism

Reasons for engaging in deliberate plagiarism are diverse, but there are some common themes.

Some have pointed to the increasing commoditization of higher education as being associated with students seeing their degrees as products and plagiarizing as the most efficient avenue to goal attainment. Also, students who feel overburdened may plagiarize because they feel they cannot get assignments completed otherwise. Some students claim they do not care for their classes or their instructors and plagiarize out of disrespect for or defiance toward a program of education that seems meaningless and impersonal. A related concern is that with many higher education institutions increasing class sizes in order to adapt to tight budgets, instructors are unable to establish the trusting relationships with students that serve as a deterrent to plagiarism and other forms of academic misconduct. When these factors are combined with a perception that plagiarizing is a relatively low-risk activity that is infrequently detected and/or penalized, plagiarizing can be seen as a reasonable academic strategy.

Some individual and group differences have been observed in plagiarism. For example, international students studying in English-speaking countries have been identified as being at greater risk of plagiarizing than their domestically studying peers. Various explanations have been offered for this risk, including the greater difficulty of writing essays in an unfamiliar language, pressure to succeed in an unfamiliar academic and social context, lack of experience and skills in essay writing, and sometimes a different cultural attitude toward ownership of words and ideas. Students who come from cultures with a greater emphasis on memorization and a lesser priority on critical thinking about source texts might experience discomfort with expressing personal ideas that are critical of the experts.

Some, but not all, research has suggested that academic dishonesty, including plagiarism, is more prevalent among male than female students, and in some disciplines (such as business) more than in others (such as humanities).

Recent personality research has indicated that both self-report academic dishonesty and naturalistic plagiarism (as detected by computer software) are associated with psychopathic personality traits, that is, the tendency to be manipulative, callous, irresponsible, and to have antisocial tendencies. This research has also indicated that

students with higher levels of psychopathic traits are less deterred than other students by the fear of getting caught.

### Detecting and Preventing Plagiarism

Although the Internet has made the commission of plagiarism easier, it has also made the detection of plagiarism easier. Instructors can now easily search for distinctive word strings from student papers. In addition, some institutions use commercial plagiarism detection software (for example, TurnItIn), in which student papers are compared to all other student papers in the database, as well as to Internet content that is publicly accessible (that is, not password protected) using search engines. Thus, many paper-mill essays will not be included in the database unless previously submitted to the data bank by another student.

In order for an institution to be seen as credible in its plagiarism policies, students should be able to feel confident that when plagiarism has been committed it will be addressed in a fair and systematic fashion. Students accused of plagiarism should be part of the investigation and provided with the opportunity to challenge evidence presented. For first-time and relatively minor infractions, some institutions take a purely educational approach, with escalating consequences for repeat offenders and larger-scale plagiarism.

Although the detection of plagiarism as well as a fair, consistent, and transparent approach to disciplining students who plagiarize are important, there are also educational practices that can be useful in the prevention of plagiarism. One such practice is to change assignments every time a course is taught, so that students are not tempted by having access to the work of previous students who were presented with the same selection of case studies or essay topics. Assignments can also be created in such a way that they call upon students' integrative abilities (for example, compare and contrast how two models of child development would explain the behavior of a character in a novel) and are unlikely to be readily available on the Internet or from other students. Another option is to have progressive "check-in" points in order to ensure that students are working in advance toward a final product, thus avoiding plagiarism that results from last-minute panic.

In order to foster a culture of academic honesty, many colleges and universities have introduced honor codes. Honor codes can take different forms, but in general, students commit to uphold their institution's values around academic integrity. Some institutions and/or instructors require students to submit a signed commitment to academic integrity with every written assignment, whereas others have students make a global commitment, generally in their first year of studies. In general, the honor code approach seems to be effective in reducing plagiarism and other kinds of academic misconduct, particularly when the institution's definition of academic integrity is very clear, as is the importance of this shared value.

### Conclusion

Although there is some evidence that plagiarism is on the rise, there is much that can be done to prevent plagiarism, including clearly communicating definitions of plagiarism, using a thoughtful approach to creating assignments, establishing an institutional culture of academic honesty, and providing a transparent process for disciplining those who plagiarize.

## Plants

In 1793, researchers discovered that some plants offer no reward to their pollinators, relying instead on deception for pollination. Deceptive plants possess traits that signal rewards they do not offer, such as food, mating opportunities, refuge, and oviposition sites. An exception is plants that do not falsely offer rewards but elicit a territorial response in certain insects. Pollinators can learn to discriminate between rewarding and deceptive plants, but plants resist this learned avoidance by exhibiting significant variation in traits.

### Plant Deception

Angiosperms, commonly referred to as flowering plants, are the most diverse group of land plants, with over 350,000 species occupying nearly every habitat on Earth. Roughly 7,500 are pollinated through deceit and, of these, approximately 6,500 are in the orchid family (*Orchidaceae*). Although deceptive flowers suffer reduced pollination success compared with rewarding species, deception remains common, and recent phylogenetic evidence has suggested that deception may even be ancestral in orchids or have evolved early in their history. One hypothesis to explain the evolution and maintenance of deception in plants is that they are able to utilize the resources that would be allocated for nectar production in other aspects of their survival, such as overall growth. Another more empirically well-supported hypothesis is that their deception encourages cross-pollination.

Increasing the likelihood of cross-pollination is beneficial because self-pollination has a negative impact on fitness and can cause reduced genetic variation or even inbreeding depression. Orchids

are especially susceptible to losing reproductive opportunities because their pollen is typically packed into masses called pollinia, which can be removed by a pollinator in a single visit, thus rendering self-pollination problematic. This might explain why deception is so prominent in orchids; nearly one-third of orchids offer no rewards.

Although it has not been well established, it is assumed that pollinators’ visits to deceptive flowers will be brief and few. Whereas pollinators typically visit many flowers on the same rewarding plant, they are less likely to investigate multiple flowers on a deceptive plant, reducing the likelihood of pollinator-mediated self-pollination.

These nonrewarding plants most commonly use food deception by resembling rewarding species either generally or specifically. Another relatively common method is sexual deception, a system in which plants mimic the females of pollinator species in order to attract males. Other forms of deception present in some species are less common and have received less empirical support. They include the use of brood-site or shelter imitation, in which plants attract pollinators seeking oviposition sites or refuge; “pseudoantagonism,” in which plants exploit the territorial behavior of some pollinator species; and “rendezvous attraction,” in which plants resemble and grow near rewarding plants, and are pollinated by males searching the flowers for foraging females.

### Food Deception

The vast majority of deceptive plants engage in food deception to attract pollinators. Some species in the arum (*Araceae*) and birthwort (*Aristolochiaceae*) families, among others, exploit carrion flies and beetles looking for food by resembling carrion. Some plants that have male and female flowers deceive pollinators because the male flowers offer rewards and the female flowers do not. Examples of this can be found in the palm (*Areaceae*), aster (*Asteraceae*), and gourd (*Cucurbitaceae*) families. However, most plants utilize what is known as “generalized food deception,” resembling the general features of a rewarding flower without a specific model.

Generalized food-deceptive plants may use showy inflorescences, floral colors, scents, nectar guides, and spurs (appendages that typically contain nectar in rewarding plants) to attract

The *Amorphophallus konjac*, or devil's tongue, engages in food deception by smelling like rotting carrion. This odor is irresistible to carrion-feeding insects, which are tricked by into visiting the flowers (and therefore transporting pollen) under the illusion that it is a promising place to obtain food or lay eggs.

pollinators. Food-deceptive plants also tend to flower early in the spring, exploiting pollinators that are just emerging from hibernation and are naively investigating all flowers in search of food. A potential explanation for the development of generalized food deception is that pollinators have pre-existing sensory biases for certain traits, and plants that possess these traits are favored during selection.

Visual signals appear to be the most important floral cues for food-deceptive species. For example, various insects are known to be attracted to contrasting colors, the color yellow, and ultraviolet wavelengths, all of which are common in food frauds. Also, bumblebees show a preference

for flowers of similar color to one that they have just successfully foraged on and seem to generally prefer violet.

Another potential reason for the success of generalized food frauds, known as the magnet species hypothesis, is that deceptive plants may benefit from growing near rewarding species, even if they do not resemble them, because of the increased number of pollinators that will be attracted to the area. However, they must rely on generalized pollinators: ones that will visit any flower. On the other hand, some insects form reliable associations with certain plants, and for deceptive species to be pollinated, they need to accurately mimic those rewarding plants.

### Plant Mimicry

In order for even a close resemblance to be considered mimicry there are a number of requirements which must be satisfied: (1) the mimic and model must overlap in distribution and interact with the same receivers, (2) the mimic should be less abundant than the model within the same area, (3) the mimic should have higher reproductive success in the presence of the model than in its absence, and (4) the mimic must resemble the model closely enough that the receiver is unable to discriminate between them. Plants that meet these requirements are known as Batesian mimics.

Commonly, the term *Batesian mimic* refers to a palatable species that closely resembles an unpalatable model, so that a mimic benefits when a predator mistakes it for the model. Botanists have argued that this term is equally applicable to mimicry in plants because the driving processes are the same: plant mimics benefit (that is, are more likely to be pollinated) if receivers mistake them for the rewarding model. Batesian mimics, overall less common than generalized food-deceptive plants, are especially rare outside *Orchidaceae*, but some are present in the dogbone (*Apocynaceae*), begonia (*Begoniaceae*), and buttercup (*Ranunculaceae*) families. The most prominent mimics, however, are *Disa ferruginea* and *D. pulchra* in the orchid family.

Visual signals in food-deceptive plants appear to be essential for Batesian mimicry. However, olfactory signals appear less important. Research has revealed that many mimics produce only a weak odor or none at all. They may rely on the

scent produced by surrounding flowers to attract pollinators. If imperfect mimicry, such as that seen in plants that do not produce an odor, is adequate for successful fertilization, the benefits of perfecting the resemblance do not outweigh the costs. Additionally, studies have shown that some bees prefer the odor of imperfect mimics, perhaps attracted to uncommon signals. Despite any imperfections, there is evidence that plant mimics resemble their models so closely that pollinators cannot distinguish between them.

### Sexual and Other Forms of Deception

While Batesian mimicry is rare within food-deceptive plants, it is well documented in sexually deceptive orchids. In sexually deceptive systems, the female of the pollinator species is the model, the males are the target receivers, and pollination of the plants occurs during precopulatory routines or pseudocopulation performed by the pollinator. Pollination by sexual deception was first discovered in the early 1900s by two independent researchers and has, to date, been conclusively reported only in *Orchidaceae*.

Orchids utilize olfactory, visual, and tactile cues to attract male pollinators: Olfactory cues are likely the most important and are useful in long-distance attraction, but visual and tactile cues are essential for promoting pseudocopulation once the male has gotten close. Mating signals, specifically sex pheromones, are thought to be among the most species-specific signals in the insect world, pressuring orchids to specialize in the precise mimicry of one or few species. Electrophysiological tools used in conjunction with analytical chemistry allowed researchers to separate the odor compounds produced by the orchids to determine which compounds elicited behavioral reactions in the pollinators—and revealed that orchids rose to the challenge, producing chemicals identical to the sex pheromones produced by the females. Similarly, although the colors of orchids compared to the female insects look different to people, they look identical within the insect visual system.

Typically, sexually deceptive plants are pollinated by solitary male wasps, although other pollinators have been reported. Solitary male wasps are generally attracted by airborne signals, search intensely for females, respond quickly

to sex signals, mate vigorously, and are polygynous—all factors which increase the likelihood that a male will pollinate an orchid through pseudocopulation. Some plants, like the orchid *Chiloglottis trapeziformis*, capitalize on the preferences of their primary pollinator. In this instance, the males of the targeted thymine wasp species prefer females of larger body size, which produce greater amounts of scent. *Chiloglottis trapeziformis* has flowers that are larger than the body size of the female wasps and produces up to 100 times more chemical signals than the females.

In addition to food and sexual deception, other types of deception are also seen among plants, but are less common and have received less experimental support. Some species within *Orchidaceae*, *Aristolochiaceae*, and *Araceae* employ brood-site imitation to attract pollinators through a general resemblance to desirable oviposition sites, such as carrion or manure. Some flowers utilize shelter imitation with floral tubes, which attract pollinators seeking refuge from rain or cold; however, because these tubes are likely to actually provide shelter, this may not be a deceptive strategy. Some orchids resemble intruders, eliciting territorial behavior, and are pollinated when males attack. This is known as pseudoantagonism and is thought to be extremely rare. A final type of deception, called “rendezvous attraction,” is another strategy exploiting the mate-searching behavior of pollinator males, which typically search flowers for foraging females. Deceptive species that resemble and grow near rewarding plants may be pollinated by these males searching for mates.

### Costs of Plant Deception

Although much research has been done on the types of deception exhibited by plants, there is limited knowledge of the costs incurred by pollinators when they mistake flowers, but it is hypothesized that the only costs for many species are time and energy. Carnivorous plants, which trap and consume deceived insects, are an exception. Another exception is the cost incurred by pollinator males that regularly ejaculate during pseudocopulation, potentially reducing opportunities to copulate with actual females later on.

Some species, such as the thymine wasp targeted by the orchid *Chiloglottis trapeziformis*,

may face even larger costs. The females of this wasp species are wingless, relying on pheromones to attract males for copulation and to carry them to a food source. If the males have learned to avoid an orchid patch after unsuccessful copulatory attempts, the females in the area may never successfully attract a male or, at least, will have to exert more time and energy into signaling. Females can increase their attractiveness by walking away from the patch, but this will cost time and energy as well. But even in species which suffer greater costs, it is unlikely that deception by plants will have a major impact on a population because only a portion of individuals will encounter deceptive flowers and even fewer will fall for the deception.

Despite the costs to the pollinators being minimal, pollinators still learn to avoid deceptive plants. The pollinators of generalized food frauds, for instance, are typically bees and bumblebees, which are known to be accurate and reliable in choosing flowers and quickly learn to discriminate against nonrewarding species. However, nonrewarding plants have a number of ways to prevent avoidance learning in pollinators and to increase the likelihood of fertilization. They can exhibit different degrees of deception, show different degrees of resemblance, and elicit different responses. Many deceptive plants also exhibit color polymorphism, in which two or more different color morphs are present within the same population of a species, making it even more difficult for pollinators to learn to avoid deceptive plants, even of the same species.

### Conclusion

Approximately 7,500 plant species are pollinated through deceit. Deception is most common within *Orchidaceae*, in which roughly one-third of species are deceptive. Generalized food deception, in which nonrewarding plants possess general traits that suggest they offer food rewards, is seen in a wide variety of plants. Specialized mimicry is less common in food-deceptive plants, but has been well documented in sexually deceptive orchids. Other types of deception (brood-site imitation, shelter imitation, pseudoantagonism, and rendezvous attraction) rarely occur and have received less support. The costs to pollinators are believed to be minimal, yet they still demonstrate learned

avoidance. Deceptive plants resist this behavior by showing a remarkable amount of variety in deceptive tactics and physical characteristics. Further research is required into the lesser-known types of deception, the costs to the pollinators, and learned avoidance by insects.

## Plato

Unlike his teacher Socrates, who condemns all lying and deceiving (unless his use of irony is considered deceptive, a conclusion resisted by scholars), and his student Aristotle, who says that all lying is base and blameworthy (although falsely modest self-deprecating lies may be exempt), Plato (429–347 B.C.E.) explicitly endorses lying. In his major ethical and political work, *The Republic* (c. 388–375 B.C.E.), Plato provides an ethical justification for lying to

others: it is justified when it benefits them and/or when it stops them from harming others. Thus Plato defends paternalistic lies and protective lies. Importantly, however, these lies are never lies about (true) reality. Lies about (true) reality can never be justified.

Plato makes a number of distinctions that are critical for an understanding of his position on lies and deception. First, Plato distinguishes between falsehood in the soul and falsehood in words.

A falsehood in the soul is a false belief about (true) reality, which includes ethical reality, held in that part of the soul that rules over the rest of the person, namely, his or her reason. Having a false belief about (true) reality is harmful to that person; hence falsehood in the soul is always “hated.” This is what Plato calls a “true falsehood.” There is never a justification for a true falsehood, not even a true falsehood told to one’s enemies. The lies and deception that Plato endorses in *The Republic* are not true falsehoods.

A falsehood in words is merely a “copy” of a true falsehood. It is not a falsehood about (true) reality. It is possible for a falsehood in words to be “useful,” that is, beneficial, as opposed to harmful. When it is “useful” it is not “hated,” that is, it there is a justification for it. The lies that Plato defends in *The Republic* are falsehoods in words (only).

## Two Kinds of Falsehood

Plato distinguishes between two kinds of falsehood in words: a *myth* and a *lie*. This is the second distinction. People who do not know the truth about the past tell a myth. They create a myth, making “the false as much as possible like the true.” A myth is “useful,” that is, beneficial, and hence is justified. Myths are not intended to be believed and do not aim at a particular truth. They are falsehoods in words that are not lies, and they do not stand in need of the same defense as lies. By contrast, a lie is a falsehood in words in which the tellers know the truth and do intend the falsehood to be believed. Lies therefore stand in need of a defense.

Plato distinguishes between two kinds of lies: a lie that aims at truth and a lie that aims at falsehood. This is the third distinction. A lie that aims at truth is a lie in which people are led to believe something that is true by believing a falsehood,

albeit not a falsehood about (true) reality. The most famous example of a lie that aims at truth is the “noble lie” in Book III of *The Republic*. This is the “needful falsehood” told by the rulers to the citizens that the citizens were born from the womb of the motherland and that the god mixed gold with the souls of some to create the class of rulers (philosophers), mixed silver with the souls of others to create the class of army and police force (auxiliaries), and mixed bronze with the souls of others to create the class of craftspeople and farmers (producers).

Although this is a falsehood about their origins, it is not a falsehood about (true) reality, and it aims at a truth, namely, that people have radically different innate capacities that make them suited for very different occupations in a state. This is a truth that citizens would not believe without being told a lie. Acceptance of this truth will make for a happier state. Hence, the “noble lie” about their origins is told to the citizens for their benefit. It is a paternalistic lie.

Lies that aim at falsehood are “useful as a medicine for averting evil.” Here it is necessary to understand the difference between gods and people. While both gods and people avoid all true falsehood, it is only gods who avoid all falsehood in words and hence avoid all myths and lies. A god knows the past, does not fear any enemy, and does not have friends who are foolish or mad. Hence, it is never “useful” for a god to use falsehood in words. A god never has a reason to create a myth or to tell a lie of any kind.

People do not know the past. Hence, it is “useful” for them to create a myth. People also have enemies who would do them harm, whom they fear. People also have friends who “through madness or some folly . . . undertake to do something evil,” whom they both fear and fear for because they are concerned about their welfare. Lies to enemies or to threatening friends aim at creating a false belief in the enemy or the threatening friend, and not to true belief. However, they do this only in order to avert an evil to the teller, the person lied to, or to others. These lies are not “hated,” that is, they are justified. These lies are protective lies and/or paternalistic lies.

The most famous example of a lie that aims at falsehood is the lie told to the mad friend in Book I. Here Plato argues that if one receives weapons

from a friend in his right mind, who subsequently becomes mad and demands them back, then one would be justified in keeping the weapons from the mad friend and not telling “the whole truth” to the mad friend (such as where the weapons are), in order to prevent him from harming himself, oneself, or others. Although such a lie aims at creating a false belief in the mind of the mad friend, it is not a false belief about (true) reality, and it averts an evil. It is a protective and paternalistic lie.

The most infamous case of a lie that aims at falsehood is the lie about the state’s eugenic practices in Book V, which Plato introduces by saying, “The rulers will need to use a quite considerable amount of falsehood and deception for the benefit of those ruled.” The rulers will arrange marriages amongst the auxiliaries so as to maximize breeding by the best and minimize breeding by the worst. The defective offspring of the former, and all the offspring of the latter, will be kept out of the auxiliary class. This will insure that “the race” of the auxiliaries is “kept pure.”

Some auxiliaries will therefore not have children among the younger generation of auxiliaries. However, the rulers want all of the auxiliaries to look upon all of the younger auxiliaries as their children and want all of the younger auxiliaries to look upon all of the older auxiliaries as their parents. They also want each generation of auxiliaries to look upon each other as siblings. This will create unity in the city because each guardian will “consider everyone he meets as a brother or sister or father or mother or son or daughter, or their descendent or forebear.”

This unity and purity of breeding cannot be achieved without lying. The rulers will therefore lie to the auxiliaries that all marriages are decided by lottery and will secretly not bring “the offspring of inferior parents, or any others who may perhaps be born defective,” to the nursery in the city that holds the other auxiliaries’ children. Instead they will conceal them “in a secret and out-of-the-way place.” Because these lies create a unity that benefits the citizens, these lies are also paternalistic lies, told to those who are not, or not yet, rulers.

## Plausibility

Plausibility, typically defined as having the quality of appearing believable, persuasive, and valuable, is one of the factors that can help people discriminate truth-tellers from liars. Research has been conducted in 60 interviews to analyze the plausibility of truth-tellers and liars’ stories, and truth-tellers’ statements and answers were found to be more plausible than those of liars. Based on the factor of plausibility, 72 percent of the truth-tellers and 74 percent of the liars were correctly classified. Although there was no difference in the amount of details between truth-tellers’ and liars’ statements, liars’ statements were less plausible than that of truth-tellers.

Contradictions and spontaneous corrections could account for the plausibility of lying to some extent. These two factors could help determine whether or not a statement is plausible. For

example, truth-tellers' statements have fewer contradictions and more spontaneous corrections, which can make their statements sound more plausible. Therefore, plausibility is negatively related with contradictions and positively related with spontaneous corrections.

### A Subjective Cue

People usually depend on plausibility to distinguish lying from truth. However, plausibility is a subjective cue. Different lie detectors might interpret the same lie differently based on the plausibility of that lie. It is hard to draw the line between plausible and implausible. Perhaps the judging of plausibility could be more accurate when other objective factors are considered.

In addition, people not only use plausibility as a factor to determine whether others are lying, but they also use latency, a statement's vagueness and consistency, another party's smiling, as well as postural shifting and grooming to help them discriminate liars from truth-tellers. For example, when people give plausible answers, the hesitations before their answers are longer, and the answer itself is often overly long.

Plausibility of account is a verbal content behavior. Verbal content behaviors are easier to control than nonverbal behaviors. However, plausibility of content is associated with truthful contents most of the time, whereas other verbal content behaviors, such as contradictions and slips of the tongue, are indicators of lying and deception. Therefore, the verbal cues associated with truthfulness are more controllable, and liars can use many verbal content behaviors to create more credible and plausible accounts. Furthermore, liars also believe they are able to present greater plausibility, logical consistency, and response length than others when they try to provide a convincing account.

Especially when there is an opportunity for liars to develop a deceptive response, the planned lie is more plausible than spontaneous lies, and less likely to be detected. Time and opportunity are important for liars. They not only help liars develop a response with more plausible verbal content but also allow liars to inhibit nonverbal behavior cues, because nonverbal cues could be the main factor that distinguish planned lies from spontaneous lies. Planning increases the

effectiveness and plausibility of lies, and makes planned deceptive responses more like spontaneous truthful responses.

A lie must have narrow plausibility to qualify as an assertion. Bald-faced lies do not need to have wide plausibility, which is the credibility relative to one's total evidence. But narrow plausibility is required by all assertions to at least make other people understand. When there is doubt about the plausibility of that assertion, liars might adopt sober tones and serious faces to evince sincerity.

Plausibility is also known as "plausible deniability." The term *plausible deniability* was coined by the Central Intelligence Agency during the John F. Kennedy administration, and was used to explain how information was withheld from high-level supervisors so that they would be shielded from unlawful or dishonest events. Often, plausible deniability is used to describe how instructions are passed down from a superior to an underling. If these instructions become public, then supervisors can deny any involvement. In turn, this lack of proof or connection to the supervisors would make their denials plausible or credible. Often, deniability is associated with politics or spying and can refer to how the actions of one person cannot be connected with the person executing orders. "Plausible deniability" can relate to any behavior that does not leave any evidence of misconduct or cruelty.

Plausible deniability is a legal concept and is defined as a lack of proof to establish an accusation. Evidence varies in criminal and civil cases. Most proof must be established beyond a reasonable doubt. Sometimes political officials may deny certain statements or actions, especially when there is circumstantial evidence. Yet, the term *plausible deniability* is typically related to espionage and is intended to hide the truth from the general public.

## Poker

Poker is a popular noncooperative, multiplayer card game that involves betting on who has the better set of cards, typically for some economic advantage (for example, money). Optimal strategies for betting are obscured by imperfect information as well as uncertain and random outcomes. Lying and deceiving one's opponents is a fundamental principle practiced by all experienced poker players.

One common strategy poker players use is bluffing or trying to convince other players that one has either a better or worse set of cards than one actually has. Research on the moral permissibility of lying has shown that in certain contexts, like games of poker, people form an implicit social contract that permits lying to one another. Thus in this context, lying is not seen as threatening to one's sense of a moral self or to one's social relationships because it has been sanctioned by others.

### Research on Poker

A large body of research has focused on the probabilities of winning and the timely use of bluffing behavior. Players typically are not rational thinkers, despite previous experiences that should inform their current decisions. More specifically, contrary to learning theory, people tend to bet

more money when they should stay and quit the hand more often when they should continue. Furthermore, based on mathematical models of risk, informed poker players do not raise as frequently as they should, and uninformed players call too frequently. To be successful, players instead should strike a balance between aggressive tactics and restraint, and the optimal strategy is to call a potential bluff half of the time.

Which half, however, is up for debate. Knowing when to bluff, mathematically, is only part of the equation—knowing how to communicate competently with the other players may be equally important. Taking these factors into consideration, computer models have attempted to produce a program that can win against the best human players. To date, however, no advanced model of human intelligence has defeated human players, perhaps because such programs cannot account for idiosyncrasies in verbal and nonverbal communication.

Another body of research is dedicated toward detecting "tells" or leakage behaviors indicating that a player is a lying. Several factors may account for why it is so challenging to determine when someone is bluffing. Poker players may lack certain visible signs of deception because they feel no guilt when lying, due to the social contract permitting them to do so. Alternatively, it may depend on the stakes. Players betting their remaining money have higher stakes and may leak signs of deception; whereas players who are betting lower or inconsequential amounts may not fear losing. Other factors may include the level of expertise of the player, the amount of practice the player has at bluffing, or the initial reaction to the cards dealt.

Some research has examined physiological changes when bluffing in a poker context and has found that measures of stress predicted bluffing behavior 71 percent of the time. Specifically, using variation in skin conductance and voice pitch, the researchers were capable of identifying high-stress situations, which, in turn, predicted bluffing. Methodological idiosyncrasies, such as comparing skin reactivity to a data point after the poker hand is completed and the short duration of speaking (for example, "call" or "hit"), however, preclude this research from more real-time analysis of lie detection in poker.

Individual differences also may be related to lie detection abilities in this context. For example, in one study although people with dysphoria or sub-clinical depression were unable to explicitly identify when professional poker players were bluffing, they disliked the pros more when they were bluffing than when they were not. In other words, they implicitly detected that the other person was not trustworthy. Future research needs to investigate this relationship and other personality factors that could affect lie detection in poker situations.

Despite the sizable literature on deception in poker, little research has examined the psychological factors that are utilized in poker, such as various bluffing contexts or strategies. For instance, is bluffing more advantageous in high- versus low-stakes (for example, all-in versus minimal) betting scenarios? Are people more successful when they try to make their opponents believe they have better cards than they actually have or when they try to convince others that they have worse cards than they actually do?

The majority of research on poker has focused on the probabilities of betting versus bluffing in an attempt to maximize the win-loss ratio, but no model has been designed that can win against a professional player. Some research suggests that detecting bluffing in poker may be function of leakage, physiological reactions, or individual differences.

## Polygraph

A polygraph, commonly called a lie detector, is literally a device for graphically displaying multiple physiological measures of human arousal simultaneously (for example, blood pressure, heart rate/pulse, the skin's electrical conductance via varying levels of water being present). As such, it provides a window into a participant's physiology during interrogations. Lies can cause physiological reactions (that is, stress) that can be monitored with or without instrumentation. Though much research on polygraphs focuses on whether they are completely accurate in determining whether individuals are lying or not, the most successful applications are as aids in eliciting verbal admissions from suspects, rather than providing indisputable evidence on their own. Rarely admissible as prosecutorial evidence, polygraphs typically are not required by courts because to do so would force individuals to provide evidence against themselves. Polygraphs are, none the less, often used for security checks and as part of the employment process for high-security clearance positions in government, intelligence, and military organizations.

Lies are a specific form of deception and have the potential to cause physiological reactions

A polygraph test is conducted using Limestone Technologies' Paragon Acquisition System. Modern polygraphs use objective computer algorithms to ascertain whether there is a higher possibility that participants are lying, rather than the more subjective judgment of the administrator alone.

(that is, stress) in the liar. The more important to the liar it is to deceive the other person, the more heightened reaction the liar may have to telling the lie. With this said, highly performed, practiced, and planned lies may cause less arousal as the individual becomes used to telling them (the individual may even believe a lie after performing it many times), and spontaneous lies would cause the most stress and arousal.

As such, there are many potential reactions to telling a lie and no universal deceptive reaction, so no single unified method of detecting a lie can exist. However, there are three dimensions of a lie that provide potential deception detection: physiological reaction, observable behaviors that indicate a lack of consistency across nonverbal channels, and the verbal statements an individual makes. Single-cue approaches to detecting deception (for example, pupil dilation) have been shown to be less effective, whereas multimodal-cue approaches are not only more effective but also mirror the natural way humans process social information, providing a more synergistic total picture of an individual's behavior exhibition.

### How the Polygraph Works

First developed at the end of the 19th century, modern polygraphs use objective computer algorithms to ascertain whether there is a high possibility that participants are lying, rather than rely on the more subjective administrator's or polygraphist's judgment alone. As such, the polygraph administrator's position has rightly focused more on eliciting verbal admissions from participants, and the administrator uses the polygraph to better know when to pursue a line of questioning. Thus, the polygraph serves as a technical aid to the administrator.

The typical polygraph interview takes place in rooms specifically designed for polygraph interview purposes; participants are placed into comfortable seats, remove their shoes, and are outfitted with the equipment that attaches them to the polygraph machine or, more recently, the computer (for example, an Axciton computerized polygraph, developed for the National Security Agency in 1991 and constantly updated). The instrument consists of a sensor box and attachments monitoring the volume and rate of

breathing, galvanic skin response, heart rate and strength, and changes in lateral blood pressure. The reactions are displayed on a video monitor and may also be printed out on chart paper. The examination is scored by an algorithm (mathematical formula) developed at the Johns Hopkins Applied Physics Laboratory.

Each participant signs a release form indicating that the test is being taken voluntarily. The interview chairs are placed in direct opposition to one another with no barriers so behaviors of the entire body can be noted. The examiner's chair is positioned slightly higher than the examinee's chair so that psychological dominance can be maintained. This increases the stress reactions of the interviewee. The administrator monitors both participants' verbal and nonverbal behaviors (for example, answer delay to and/or repetition of question, arms crossed over chest, closed body position, reduced or lack of eye contact, and speech errors) and the polygraph program's data analysis to ascertain whether following a line of questioning is likely to prove fruitful at detecting deception through aroused suspicion. The more a participant believes in the validity and reliability of the polygraph device to detect deception, the more heightened the participant's stress/arousal reaction to deceptive attempts, thereby assisting the polygraph in detecting deception.

The stress responses manifested on relevant questions are averaged and compared to the "control," or comparison, questions typically asked during an earlier calibration prepolygraph phase of the interview. If there is a consistently greater reactivity to the relevant questions, the person is labeled "deceptive." If there is a consistently greater reactivity to the comparison questions, the person is labeled "truthful."

The polygraph is often viewed as a potential deterrent to dishonest activities, such as stealing, espionage and counterespionage, or lying, especially in positions requiring security clearances in which individuals know they will be subject to a polygraph. The U.S. government, intelligence agencies (for example, the Central Intelligence Agency, Federal Bureau of Investigation, and Defense Intelligence Agency), and military positions carrying high-security clearances frequently require successful polygraph interviews.

## Are Polygraphs Legal?

A goal of a polygraph interview is to have participants make verbal statements that reveal guilt, if appropriate. Courts would admit such verbal statements as confessional evidence. However, several legal systems have safeguards preventing individuals from being coerced into testifying against themselves or committing compelled self-incrimination, such as the Fifth Amendment of the U.S. Constitution, largely in response to historical situations of torture and elicited confessions. Thus, for some countries, any court-ordered polygraph constitutes compelled self-incrimination, in which suspects' own bodies are testifying against them, though this position still allows for voluntary polygraphs to play a role in courts.

As such, few court systems require polygraphs of suspects, and many courts expressly forbid polygraphs as evidence. Further, although polygraph-aided deception detection is substantially higher than unaided human deception detection or chance alone, both false positives (that is, an innocent person being found guilty) and false negatives (that is, a guilty person being found innocent) occur with regularity in polygraph use.

Other lie detectors include functional magnetic resonance imaging (fMRI), vocal stress analysis machines (for example, the MACH series), and more field-friendly tests such as muscle testing, in which the individual's own body is used to determine lies and truth.

## Primates

Deception is not a uniquely human capacity. Accounts of deception have been documented among many nonhuman primate species, including macaques (monkeys), baboons, gorillas, chimpanzees, and orangutans. Nonhuman primates

tend to exhibit patterns of deception that appear to serve two key evolutionary functions: survival and reproduction. To these ends, primates have also been observed hiding food, bluffing to avoid threat and punishment, and hiding courtship behavior from fellow primates. In other instances, primates have exhibited deception in playful ways that do not directly impact day-to-day survival or reproduction.

Deception in nonhuman primates has also been linked to the size of the brain's neocortex as well as the complexity of their social system. Given the complexity of both the form and function of these acts of apparent deception, deceitful primate behavior has spurred debate about the potential for nonhuman primates to experience consciousness, engage in higher order thought processes, and understand the mental experiences of fellow primates—responses that otherwise appear uniquely human.

Recent research has found that frequency and complexity of deception is strongly related to brain size in nonhuman primates. Particularly, it seems to be the size of the brain's neocortex—relative to the size of the animal—that is linked to deception. The larger the relative neocortex in the primate species, the more that primate species seems to deceive. In primates with very small neocortices relative to their size, such as lemurs and bush babies, there are not many recorded instances of deception. Yet, in primates with larger neocortices, such as gorillas, chimpanzees, baboons, and orangutans, many instances of complex tactical deception have been observed. The neocortex is largest, relative to body size, in humans—the only primate species unarguably known to exhibit intentional deception. These findings, however, do not answer the question regarding whether or not nonhuman primates are consciously using deception.

Nonhuman primate deception has been commonly referred to as tactical deception because it serves the function of actively deceiving others for personal gain, but is not necessarily intentional. It is also not passive, which distinguishes it from other forms of deception such as camouflage. Although tactical deception has been observed in several nonhuman primate species, the existence of intentional deception—which is commonly observed in humans—is still heavily debated. The

following examples of primate deception represent tactical deception, though arguments have been made regarding the intentionality of these actions.

### Food Deception

There are many instances in which a nonhuman primate withholds the truth and/or actively deceives other nonhuman primates as a means of increasing his or her odds of survival. Many different species of monkeys—including some brown capuchins, macaques, and spider monkeys—have been found to keep secret food sources. They also stay away from their secret food sources when more dominant monkeys (that is, the monkeys that always get first access to food) are around so that the dominant monkeys cannot find it. Some capuchins have been known to purposefully point to a location that does not contain food so as to deceive any competitors that would take it. Some will even fake disinterest in a desirable food while others are around to keep them from stealing it.

Similar behaviors have been observed in baboons, gorillas, and chimpanzees as well. When female savannah baboons notice a male baboon eating a food that is not easily obtainable, she will walk up to the male and begin grooming him. Once he becomes more relaxed, she will steal his food and run. When sitting near a dominant male gorilla, female gorillas have been known to eat leaves while secretly gathering fruit (the more desirable food) with their feet.

Jane Goodall had also witnessed similar behaviors during her observations of the chimpanzees in Gombe Stream National Park. If chimpanzees approach a banana while a dominant chimpanzee is around, the dominant chimpanzee will take it from them and eat it. The other chimpanzees can find ways around this though. Goodall observed one chimpanzee that noticed a banana but stayed away from it until the dominant chimpanzee was gone. He then approached, acquired, and ate the banana. Several instances of this type of deceptive hiding behavior have been observed in chimpanzees both in laboratory experiments and the wilderness.

Some chimpanzees will withhold information regarding the location of a food source to all others in their group. Sometimes, when a chimpanzee comes across a single piece of fruit, she

will act as though there is no food around, then calmly grab the food, keeping it hidden in her hand, and continue to walk on all four limbs. When carrying food, chimpanzees will walk on three limbs while holding the food with their fourth, so walking on all four limbs signifies to the others that she does not have any food. Other researchers have observed accounts in which a chimpanzee learns of a food source and then leads the other chimpanzees away from it only to come back later and feast.

These observations may be evidence for consciousness and intentional deception in nonhuman primates; however, skeptics argue that these behaviors could have been learned through trial and error. For instance, if a chimpanzee finds some tasty food and begins eating it in front of the others in her group, she may have the food stolen from her—forcing her to go hungry. When she finds food again in the future, she may realize that revealing possession of this food to the others means she will not get the opportunity to eat it.

### **Other Forms of Tactical Deception**

Tactical deception for survival is not just about hiding food. Orangutans have been found to hold leaves to their mouths to help emit a lower tone of warning calls, along with shaking and throwing sticks and leaves, when they are startled by predators. These actions are performed as a means of making themselves seem much larger than they really are in order to scare away predators and other potential threats.

Male chimpanzees display similar bluffing behaviors when competing for dominance with a bigger, stronger male. In these instances, the bluffing chimpanzee tends to turn his back to his rival and reflexively bare his teeth, which is a sign of fear. He will then use his hand to cover his teeth—sometimes by pressing his lips together—as a way of hiding his fear before he turns back around to confront his enemy. In one instance, primatologist Frans de Waal observed two chimpanzees fighting at the Arnhem Zoo (in Arnhem, the Netherlands). One chimpanzee hid a brick behind his back so that the other chimpanzee would be unaware of it. He then threw the brick as a surprise attack toward the other chimp.

There are also instances in which a nonhuman primate may deceive other nonhuman primates

as a means of increasing his or her probability of reproducing with a desirable mate. Competition for mates can be fiercely violent among male primates. As such, subordinate primates may mate with females in private to avoid danger. In one famous example of deception, a male chimpanzee was observed hiding his erection in the presence of a more dominant male after attempting to mate with a female. By hiding his erection, it is possible that he avoided a violent confrontation.

Young female hamadryas baboons who are supposed to mate with their male troop leader will sometimes sneak away to groom and mate with younger males. Grooming and mating with other males will enrage the troop leader, so these females have found deceptive ways to mate with younger males without their troop leader knowing. They will repeatedly mate with the younger male in a hiding place, while going and checking on the troop leader between matings—sometimes even presenting herself sexually to the leader in, what researchers believe, an attempt to minimize any suspicion from the leader. One researcher observed an instance in which a female positioned herself perfectly behind a large rock so that the leader could see the top of her head and back, but her front and arms were completely hidden. She then proceeded to groom another male while the leader was none the wiser.

There are also instances of nonhuman primate deception that occur to simply avoid punishment. In one instance, researchers observed a young baboon, in an attempt to prevent a physical punishment from his mother, looking intently to the horizon as if an enemy or predator was on its way—fooling his entire troop, including his mother, into frenzy and successfully escaping his punishment. Savannah baboons have been known to emit a predator alarm call when they are being chased by their parents or other dominant adults. Bonnet macaques (monkeys) will also emit alarm calls to prevent punishment or attack from an adult. In these cases, the use of tactical deception tricks the aggressor into thinking there is a predator nearby, which causes the aggressor to stop punishing or attacking the young primate in preparation for a predator attack.

A 2010 report from Nebraska's Omaha Zoo described an orangutan named Fu Manchu that

would use a piece of curved metal to repeatedly pry open the service door of his habitat in order to climb and lounge in the trees outside. Fu Manchu kept this bent piece of metal hidden in his mouth, curving it between his lower teeth and lip like a mouth guard. There is also the famous story of Koko, the gorilla who learned sign language, ripping a sink off the wall. When the researchers asked her who ripped the sink off the wall, Koko blamed her pet kitten.

### Is Deception Intentional?

These anecdotes and experiments on primate deception raise important philosophical questions about language, thinking, and consciousness in nonhuman primates. Intentional deception is commonly understood as normal behaviors that are performed with the intention that they will be misunderstood by an observer and result in positive outcomes for the deceiver (for example, bluffing to avoid threat, sneaking food). These definitions assume that the deceiver is not only aware of his or her actions and the consequences of those actions but also aware of the way those actions might be perceived by an observer. In humans, this perspective taking represents a higher order level of thought that gradually develops over childhood.

Because some primate behaviors appear to mimic human deception, some theorists have suggested that primates who exhibit deceptive behavior may be consciously anticipating the ways other primates will perceive their behavior. That is, primates may be able to deceive others because they possess thinking, an understanding of their own minds, and some understanding of the minds of fellow primates. However, experimental analyses regarding this have found conflicting results.

Although humans intentionally deceive others, behaviorists might argue that thought and intention is not needed to understand or exhibit deceptive behavior. It is possible that some behaviors, though they may seem intentional, were actually learned through trial and error and are thus merely instances of tactical deception. In the case of the male chimpanzee that covered his genitals in the presence of a dominant male, it is possible that on previous occasions he was struck when he was erect around females and learned to cover himself

out of habit. As such, his covering himself was not so much a conscious act but an automatic habit.

### Conclusion

A large body of research has found several instances of tactical deception across many different primate species. Deception among nonhuman primates occurs for different reasons and in different environments, such as increasing one's chances of survival and/or reproduction and preventing punishment. This evidence, however, is not sufficient to support the theory that nonhuman primates have consciousness, engage in higher order thought processes, or understand the mental experiences of fellow primates. Because of this, it can only be said that nonhuman primates are utilizing tactical deception, not intentional deception.

## Probing Effect

The probing effect is the finding within deception research that if a source is further questioned, or probed, deception detection accuracy will not improve. However, the source will be more likely to be perceived to be honest, when compared to a source that is not probed. This robust finding has been found to hold true regardless if the information presented is truthful or deceptive, if the interactants have a previous relationship, if the receiver is suspicious, or whether the individual making the truthful or dishonest judgments is an observer or a participant in the interaction.

The most common explanation for this finding is focused on the source adapting his or her behavior in an effort to appear more honest, although this explanation has encountered a great deal of criticism. Regardless of the explanation, however, the implications for deception and deception research are apparent and numerous. The method of continued questioning is a common strategy for suspicious and nonsuspicious, amateur and professional interrogators alike. Furthermore, it is presumed that continued questioning should improve the accuracy of a veracity judgment. However, the mere act of follow-up questioning, which may result from even the slightest suspicion or even curiosity, enhances the likelihood of a source being perceived as honest, even when he or she is being deceitful.

### Behavioral Adaptation Explanation Debate

The explanation most commonly accepted for the probing effect is the behavioral adaptation explanation (BAE). The BAE speculates that as the source is probed, the individual will pick up on any potential suspicion from the receiver and, as a result, strategically adapt his or her behavior in an effort to appear more honest. It is reasoned

that through the extended interaction, the source may think that the receiver is suspicious of the veracity of the responses because of the extra or probing questions. Thus, the source will behaviorally adapt in an effort to assuage the suspicion. There is, however, a contentious academic debate around the empirical support of this explanation.

The BAE postulates a three-link causal chain: (1) probing with additional questions alerts the message source that the receiver is suspicious, (2) the recognition of potential suspicion causes the source to purposefully and strategically adapt his or her behavior in an effort to appear more truthful, and (3) the change or adaptation of the source's behavior results in a more honest perception of the receiver, relative to a nonprobed source.

Criticisms of the BAE are focused on two main areas. The first is the lack of clarity around which behavioral cues are altered by probed sources in an effort to appear more honest. There is a debate over what constitutes stereotypical cues to deceit, whether these are in fact the behaviors that are adapted, and if laypersons would possess the level of information required to alter such behaviors in an effective manner. Second, there is considerable concern around the empirical support of the predicted links that compose the BAE. There is trepidation about a potential overemphasis on what support has been found and perhaps misinterpretation of a variety of statistical tests utilized to assess the data collected.

Responses to the criticisms have focused on concerns that the critiques are based on an inaccurate context of probing and based on earlier, less developed assessments of the probing effect and the BAE. Specifically, the critiques do not account for the necessary perceived suspicion of the receiver by the source and only assesses the earliest of studies testing it. The responses also cite evidence from various other areas of communication research, including deception research, that demonstrate behavioral adaptation does in fact occur over time between interactants. Moreover, this adaptation is not necessarily limited to stereotypically deceptive behaviors. Additionally, responses to criticism also express concern that the statistical techniques utilized to assess and criticize the BAE are inadequate.

One explanation for the continued endurance of the BAE despite strong criticism is its fit within

the typically accepted focus of communication theory. Specifically, the BAE embodies the strategic nature of communication that most communication scholars abide by.

### Probing Heuristic Explanation

A cognitive heuristic referred to as the “probing heuristic explanation” has been offered as an alternative explanation of the probing effect. That is, there is evidence that behavioral adaptation is not necessary for the probing effect to occur; rather, it may be because of factors that elicit heuristic processing in the receiver who ultimately provides the veracity assessment. For example, studies inducing various levels of active processing found that individuals who engaged in greater heuristic processing were more likely to judge probed sources as honest than individuals induced into more active processing. This finding suggests that the probing effect is more likely due to the cognitive state of the receiver, rather than a behavioral reaction of the sender.

### Implications for Deception

Despite an enduring academic debate over the explanation for the probing effect, it remains a robust piece of deception and deception detection research. Specifically, it is consistently found to be the case that a probed source is more likely to be seen as honest and truthful than a nonprobed source. This appears quite counterintuitive when one considers the response to piqued suspicion or curiosity, which typically would be further questioning. This has major practical implications given that interrogations are common practice for amateur and professional deception detectors alike, and it is presumed that further questioning will result in improved detection accuracy. However, merely being aware of a tendency to judge a probed source as more honest compared to a nonprobed source, especially under increased heuristic processing, may allow for incorrect judgments to be noticed and corrected.

## Projection

The social and personality psychology literature is rife with demonstrations of the ways in which people self-deceive in the interest of maintaining favorable self-views. The desire to enhance and protect one’s self-image is among the strongest of individuals’ self-motives. While accomplishing this goal is certainly a multimechanistic process, one early explanation of how individuals protect and enhance the self advanced the concept of projection.

Originally proposed by Sigmund Freud as an ego-defense mechanism, projection involves perceiving one’s undesirable qualities in others as a means of avoiding seeing these same faults in the self. The Freudian view assumes that such projection occurs subconsciously, as doing so effectively deceives the ego from realizing that the person possesses the negative disposition. Thus, in its original psychoanalytic conceptualization it was argued that people were unaware of possessing the unfavorable characteristics they projected onto others. Supporting this perspective, early research showed that people who were evaluated by others

as possessing an undesirable characteristic—and importantly, lacked awareness that they possessed this trait—were more likely to see others as possessing this characteristic than were those who were keenly aware of their shortcoming.

However, succeeding social-cognitive interpretations of the phenomenon, which label the process defensive projection, challenge the notion that individuals must not be aware of possessing the undesirable trait in order for projection to occur. To the contrary, one investigation showed projection to be strongest among individuals who were mindful of possessing the projected quality. Thus, the role of conscious awareness in eliciting classic projection has been debated. Nevertheless, traditional and contemporary conceptualizations alike agree that defensive projection occurs when people seek to defend their self-image by denying the possession of certain undesirable qualities, which in turn increases the likelihood that these same characteristics will be perceived prominently in others.

### Research on Projection

Early investigations effectively established evidence for basic projection effects. Yet, much of this work was criticized for lacking the methodological rigor necessary to conclude that defensive projection was indeed responsible for the effects observed in these studies. Despite its psychodynamic roots dating back to the early 1900s, methodologically sound evidence for projection, and its underlying mechanisms, did not emerge until much later. One intuitive model has been advanced by Leonard Newman and colleagues, which asserts (as did Freud) that projection begins with the motivation to avoid recognizing threatening qualities in the self. This motivation, they showed, leads people to actively suppress any thoughts suggesting that they possess the unfavorable trait.

As a growing body of social-cognitive evidence has shown, however, people are rarely successful in these suppression attempts. Rather, the ironic effect of thought suppression is that people often become extra-sensitive to thoughts related to the unwanted content. Thus, Newman and colleagues argue (and provide evidence) that projection occurs when the enhanced accessibility of the undesired trait increases the likelihood that it will be incorporated into impressions formed of other

people (even when one successfully suppresses seeing the fault in the self).

Experimental evidence for the ego-defensive property of projection has also been obtained. These studies show that individuals afforded the chance to project their undesirable traits onto others subsequently experience decreased accessibility of thought content related to this attribute and are less likely to report possessing this trait than are those who are not provided the opportunity to project.

Other investigations have explored onto whom people focus their projection. One common target is members of stereotyped groups. Projection most effectively occurs when it seems warranted to describe another person as possessing an objectionable characteristic. As such, members of negatively stereotyped groups are often perceived as reasonable targets, particularly when the stereotype includes the undesirable trait being projected. Accordingly, studies have shown that experiencing self-threat in an important personality domain (for example, intelligence) enhances the accessibility of stereotype-relevant knowledge related to the unfavorable quality (that is, student athletes as unintelligent). This augmented accessibility, in turn, increases the likelihood that projection will be focused on members of this group rather than on nonstereotyped individuals. The projection that occurs following such ego threat is domain specific. In other words, stereotyped individuals are not evaluated less favorably overall but only with regard to possessing the undesirable quality that people wish to deny in themselves.

### Other Forms of Projection

In addition to classic defensive projection, other forms of projection have also been documented. For example, attributive projection describes the general tendency for people to project their attributes onto specific others irrespective of wishing to deny these characteristics in themselves. In a typical experiment, participants are informed that they possess particularly desirable or undesirable traits. Thereafter, these qualities are more likely to be attributed to others than when such feedback is not provided.

As with classic projection, attributive projection manifests selectively in ways that enhance

individuals' self-esteem. For example, although attributive projection occurs for both positive and negative characteristics, the effect is particularly apparent for undesirable traits. Such strategic projection minimizes the threat posed by objectionable qualities by instilling in people the perception that their flaws are common. Likewise, onto whom individuals project their traits is also selective. People are more likely to project their attributes onto liked rather than onto disliked others, especially in the case of undesirable characteristics. Projecting one's positive qualities onto well-liked others reaffirms that these attributes must be favorable, while doing so for negative traits diminishes their threat potential by reassuring that, if other highly regarded people also share these qualities, they must not be that detrimental.

A Washington Wizards Girl performs during the Washington Wizards versus Minnesota Timberwolves basketball game in Washington, D.C., March 5, 2011. One common target of projection is members of stereotyped groups, which are seen as reasonable targets. For example, cheerleaders, like athletes, are often accused of possessing traits of low intelligence or snobbery.

Work on another variant of projection—coined the false consensus effect (FCE)—has shown people to overestimate the commonality of their attitudes, behaviors, and traits among the general population. While a number of nonmotivational explanations for the FCE have been advanced and supported, the FCE is also the product of ego-protection concerns. For instance, people typically show more false consensus for attributes and attitudes they deem undesirable than for those they perceive as favorable. This strategic pattern allows individuals to maintain the perception that, whereas their strengths are somewhat rare and unique, their shortcomings are shared and normative.

### Conclusion

Historical and contemporary research alike illustrates that projective techniques—including classic defensive projection and its subsequent derivatives—facilitate people's self-protection agenda. By operating beyond explicit awareness, these processes effectively deceive individuals into perceiving fewer shortcomings in themselves than truly exist and greater inadequacies in others when their own flaws are readily apparent.

## Psychoanalysis

Psychoanalysis was developed by Sigmund Freud around 1895, but it has since evolved into a diverse and internally complex combination of theoretical approaches, institutions, and clinical practices conducted in various parts of the world. Nonetheless, this diversity is unified by the common postulate of the unconscious. This hypothesis has profound implications for notions of lying and deception. Arguably the most sophisticated theorist on the topic of lying and deception is the French psychoanalyst Jacques Lacan, whose ideas show how psychoanalysis institutes what is almost a reversal of traditional understandings of lying and deception.

Psychoanalysis in general offers a very different perspective from much of the mainstream psychology of lying. While the latter focuses on the conscious, intersubjective motivations behind deceptive but fundamentally social behavior, such as "white lies" and "face-saving" lies, psychoanalysis does not focus directly on the socialized intentions of the speaker at all. Instead, it locates truth—understood as cause in something like the medical, etiological sense—in a region actively excluded from consciousness by the forces of repression, namely the unconscious.

Thus, deception from a psychoanalytic perspective becomes primarily self-deception. Its bracketing out of the social aspects central to the psychology of lying allows psychoanalysis to isolate the ego, the seat of conscious selfhood, as

a defense (a lie of sorts) against the truth of the unconscious, which in the Freudian tradition is fundamentally sexual.

When treated as an abstract social and perhaps even universal psychology, rather than as a clinical practice taking place only under certain conditions, this approach can reduce psychoanalysis to a violent, hermeneutic device that finds the "truth" of an Oedipal unconscious everywhere. Though cultural theorists in academia have found this a useful way to produce "psychoanalytic" readings of novels, paintings, and films, it has understandably invited criticisms from philosophers engaging with psychoanalysis on a primarily epistemological level.

However, the rich complexity that psychoanalysis has brought to debates about lying and deception can only be appreciated if it is rooted in clinical practice. It is from there that analysts from Sigmund Freud to Carl Jung, from Melanie Klein to Donald Winnicott, have considered the impact of lies and deception on transference (traditionally understood as positive and negative feelings directed toward the person of the analyst) and on therapeutic outcomes (again, traditionally understood on a medical model based on a reduction in pathological symptoms).

### Lacan on Lying and Deception

The most sophisticated theorist of the psychoanalytic perspective on lying and deception, however, was arguably the French analyst Jacques Lacan. Drawing on the natural world, Lacan recognized that deception is a fundamental mechanism in evolutionary adaptation at the phylogenetic or species level, as well as in reproductive behavior at the ontogenetic or individual level. This can be seen in everything from the camouflage of chameleons to the mating rituals of numerous bird species (with males, for example, fluffing up their feathers to appear larger), from eye-like patterns on the wings of butterflies to predators mimicking the calls of their prey to lure them nearer.

In their own "mating rituals" and intersubjective relations generally, humans are no exception to this. For Lacan, the "imaginary" ego is a tissue of deceptions that gives the subject an "imago" or image of selfhood broadly legible at a social level. However, humans are also very different from animals in their unique capacity for speech.

It is only this ability to construct symbolic systems that makes lying per se, as opposed to deception, possible. Though capable of exquisite camouflage, the animal is not capable of the double or even triple bluff.

Lacan often illustrated this with an example taken from Freud's *Jokes and Their Relation to the Unconscious* (1905):

Two Jews met in a railway station in Galicia. "Where are you going?" asked one. "To Crakow" was the answer. "What a liar you are!" broke out the other. "If you say you are going to Crakow, you want me to believe you are going to Lemberg. But I know that in fact you're going to Crakow. So why are you lying to me?"

This example seems to suggest a vertiginous oscillation between truth and deception, made possible by a symbolic system with exchangeable elements ("Crakow" for "Lemberg" and vice versa). Unlike the primarily visual *trompe l'oeil* of deception, then, lying requires a combinatory system operating by means of formal relations, not resemblance or correspondence to a referent. It is no coincidence that Lacan also made early use of game theory, in which the logic of move and countermove discernible in this joke is mathematically modeled.

From a clinical perspective, however, this joke might be interpreted differently. The inability to finally settle the oscillation between lying and deception could indicate traits of paranoia, in which the only certainty obtaining for this man is that he is everywhere deceived. In other words, for an analyst there is a truth to be read between the lines.

For this reason, Lacan has little time for the so-called liar paradox beloved of philosophers of language, in which the logical form of a statement such as "I am a liar" seems to scramble traditional logic. At least in the clinical setting, it would immediately be significant that the patient felt the need to lie to their analyst, quite apart from the content of this lie. This is why Lacan claims, with characteristic allusiveness, that "truth has the structure of fiction." This means that psychoanalytic truth is often presented as a lie, a story, a distortion, but that this is precisely the only form that unconscious truth can take. For example, approaching

the delusional constructions of a paranoid psychotic by simply denying his or her objective reality is known to be almost completely ineffective. Freud's term *psychic reality* already indicated the subjective durability of this other reality.

Psychoanalysis, then, does not judge "lies" for their deliberate dissimulation of the truth (as if there were only one), but reads a different truth precisely in that dissimulation. Conversely, psychoanalysis does not accept stated truths at face value, because they can be acts of self-deception that conceal their opposites. However, it is disingenuous to take phenomena largely confined to the analytic setting and extrapolate them into a global theory of truth in general.

## Public Relations

Public relations involves the promotion of an organization's identity, culture, values, and agenda through strategic outreach to relevant designated

publics. This outreach is particularly important during times of crisis within an organization. Public relations strategies often utilize traditional and social media tools to communicate an organization's messages. Unlike journalists whose idealistic moral intent is to serve the greater good, the intent of public relations is to serve the organization. Therefore, public relations professionals are not neutral media practitioners. As a result, a skeptical public often associates public relations with deception, and the industry is stigmatized as one in which lying is common practice. Most public relations representatives choose to walk the fine line of spin and not admit to lying as a professional attribute. However, some argue that lying is the currency used in the public relations industry.

At their best, public relations companies diplomatically and strategically use various communication channels, including the media, to navigate threats to brand reputation. For example, in 1982 and unbeknownst to the company, Tylenol capsules were infected with cyanide and sold. This resulted in seven deaths. Although not directly the fault of the company, the brand's reputation suffered considerably. Working with those within and outside of the company, public relations representatives helped Tylenol respond to the crisis, launch a new tamper-free design for the product, and rebuild the brand's reputation. Through productive and ethical public relations practices, Tylenol was able to rebound.

### Spin Versus Lying

While public relations practitioners are loath to consider themselves liars, they comfortably view their profession as involving spin. *Spin* is the term used to capture the ethical side of a fine line in public relations. Outright deception would involve providing a public with inaccurate information. In contrast, spin involves providing information in such a way as to guide the targeted public in the interpretation of that information. Spin involves finding a way to view and discuss an issue that helps an organization accomplish its goals strategically. Various techniques are used to spin a story in the interest of an organization while walking a fine line regarding deception.

Spin can involve withholding information at a current moment. One example of this is stonewalling. Stonewalling occurs when a spokesperson

postpones providing information that may reflect poorly on the organization.

Spin also involves tailoring a message to minimize the more injurious aspects of that message. This can occur, for example, when an organization facilitates and reports about relevant research studies. Organizations can sponsor research studies, give input into which population is studied, report only those results that reflect positively on the organization, and reinterpret research study results to downplay the negative implications of findings.

Another type of spin involves dispersal. Dispersal occurs when agents of an organization are sent directly to an affected public to provide positive information about a company. An example of dispersal is the work of lobbyists, who advocate for the goals of an organization.

The difference between spin and deception is consequential. This is because lying can have the reverse effect than desired in public relations. Public relations goals are harder to achieve once trust with a public is broken through a deceptive act on the part of an organization. Moreover, public relations representatives have been prosecuted and fined for engaging in deceptive practices. Public relations practitioners walk a fine line when it comes to deception. As a result, the ways in which organizations manage their reputation has implications for legal, political, and health issues, among other important issues. Media representations of the public relations industry often depict the struggle faced by ethical public relations practitioners.

### Media Representations of Public Relations Deception

Albeit fiction, movie representations of the public relations industry thrive on the deception connection. Movies such as *Jerry Maguire* (1996), *Wag the Dog* (1997), and *Thank You for Smoking* (2005) demonstrate the way public relations representatives spin on behalf of their employers.

Nonfictional representations of the public relations industry are arguably closer to the truth. For example, former insider Ryan Holiday published his controversial book, *Trust Me. I'm Lying: The Tactics and Confessions of a Media Manipulator* in 2012. Holiday claims to provide secrets about the public relations industry and its manipulation tactics. Prior to his book's publication, Holiday

used an e-mail list called HARO (Help a Reporter Out), which reporters use to find experts, to prove his point. He responded to each inquiry from a reporter, regardless of topic, as if he was an expert. Without detection, Holiday was able to make media appearances and contribute to news stories. The HARO “experiment,” as Holiday called it, was widely criticized and dismissed within the industry as a public relations ploy used to generate book sales.

When public relations events garner considerable media attention they become case studies that represent the industry. These events provide insight about how public relations can tread ethical lines. In some of the most well-known cases, public relations attempts to shield an organization from backlash when there are considerable health and economic concerns for the general public. However, these attempts are not always successful. Famous historic cases include the nuclear threat at Three Mile Island in 1979 and the *Exxon Valdez* oil spill in 1989.

In the Three Mile Island Case in 1979, the threat of nuclear leakage raised fervor in the public, which was further fueled by the unrelated and purely coincidental release of *The China Syndrome*, a film about a nuclear accident. Government officials such as Governor Dick Thornburgh of Pennsylvania and President Jimmy Carter helped alleviate public concern, and positive policy changes resulted from the incident. Public relations efforts were less successful in quelling concerns about radiation, which had not been leaked at dangerous levels. Three Mile Island is still synonymous with nuclear accidents in part because of the assumption that lying played a role in the messages about the incident.

During the *Exxon Valdez* oil spill in 1989, Exxon ignored mounting fear and criticism related to the health, environmental, and economic costs of the spill. Rather than seek external public relations assistance, the company relied on questionable legal advice to withhold information from the public in order to deal with the crisis. The organization’s choices in using deceptive message design in its public relations strategy heightened suspicion about the company, which contributed to the need for Exxon to pay billions of dollars in clean-up costs and criminal, civil, and punitive settlements.

Recent cases suggest that some organizations have not learned the value of public relations that stays on the ethical side of spin. This is especially unfortunate when history repeats itself and organizations continue to make similar public relations mistakes. Most recently, the BP oil spill in 2010 and the Fukushima Daiichi nuclear disaster in 2011 demonstrate that public relations is arguably least convincing when deception plays a role in its practice.

During the BP oil spill in 2010, deflection and downplaying the severity and the effects of the spill were commonplace. BP (British Petroleum) underestimated the size of the spill and tried to divert attention from the company by referring to the spill as the “Gulf of Mexico oil spill.” These artificial and ethically questionable attempts to sidestep the economic and health issues associated with the spill resulted in considerable financial cost and fostered public skepticism of the company’s public relations messages.

After the Fukushima Daiichi nuclear disaster, which occurred on March 11, 2011, the Japanese government was criticized for its poor public relations. For example, the discovery of tainted rice in Onami, Japan, in the fall of 2011 fueled concerns that the government processes for determining food safety with relation to radiation were not sufficient. The political effects of the disaster are still being experienced and distrust of the government manifested in a variety of ways. For example, people living near nuclear plants have protested perceived government deception by refusing government subsidies that they have historically been given because they are willing to live in these locations.

Case studies like these popularized in the media represent the problems that can arise when public relations strategies are deceptive. These cases demonstrate why ethical public relations strategies are necessary to accomplish the message design goals of an organization. The ability for public relations to spin, but not necessarily to deceive, is valuable to organizations in crisis, particularly when there are political, economic, or health issues at stake.

### **Lying and the Use of Social Media**

Digital public relations is a thriving industry. Organizations can use social media in particular in innumerable ways as an alternate and more

interactive outlet than traditional media. Moreover, social media tend to have less systematic and official oversight than traditional media. Social media provide new opportunities for deceptive practices by public relations practitioners. For example, fake reviews on company Web sites and exaggerations about experiences with products or services on blogs can be strategic messages designed to promote company hype.

In July 2012, Chick-Fil-A was accused of backdating a recall of a children's toy it was distributing with its meals after the licensor expressed disagreement with the company founder's religious views. Matters were made worse by rumors that the company had created a fake Facebook post by a teenage girl in support of its claim, which the company denies any involvement in and evidence does not support. Social media outlets such as Reddit publicized the controversy.

Watchdogs and gatekeepers notwithstanding, legal boundaries for deceptive practices in social media exist. Faking online product reviews and inflating numbers that indicate the popularity of a product have been grounds for legal action. One of the most well-known cases involves Universal, Sony, and RCA, who were fined for artificially inflating their video views through YouTube in violation of Google's user agreement policies.

### **Lying as an Attraction to the Public Relations Industry**

Regardless of the ethical and legal issues that are foremost in the mind of any public relations representative, droves of college students are intrigued by the public relations industry. Public relations is among the top 10 most popular majors across colleges in the United States. The potential to work for Fortune 500 companies and meet high-profile professionals and celebrities is an irresistible magnet for many college students looking for a career. Moreover, because students may share the stigmatized representation of public relations as an industry inseparable from deception, they may find the opportunity to flex their deceptive skill appealing. Low pay and slow progress up the hierarchical ladder in a public relations company do not dissuade students from viewing public relations as an attractive profession.

### **Legal Issues in Public Relations**

Various legal issues are relevant to the public relations industry and temper any organization's inclination to engage in deceptive public relations practices. Public relations practitioners benefit from understanding the legal boundaries of their profession. Regardless of the preferences of their clients, the law places limits on what takes place in the industry.

Relevant laws require accuracy and expediency in information that is revealed to the public. Some of these laws require public relations practitioners to testify against their clients. Other laws dictate restrictions related to defamation and libel when public relations strategies include a discussion, for example, of competitor organizations. Other legal issues of which a public relations practitioner must be aware involve privacy, statutes of limitations, consent, as well as restrictions related to copyrights and trademarks. These laws are intended to hamper an organization's ability to engage in deceptive public relations practices.

Even something as seemingly simple as an organization's offering of an apology to its publics can be a point of legal contention for a public relations practitioner. An apology can be viewed within a legal system as an admission of guilt and, thus, organizations may wish to strategically avoid offering one. However, some states have adopted so-called apology laws that provide organizations a measure of legal protection against self-incrimination for offering an apology. These laws address the importance of compassion for victims in times of crisis.

### **Ethics in Public Relations**

Despite the bad reputation that the public relations industry has garnered because of its association with deception, public relations is a valuable and thriving industry aided by its strong ethical stance. Consider the importance of public relations to rally support for or against various political agendas, such as foreign aid, universal health care, wars, and other domestic and international initiatives. These initiatives could not be undertaken successfully without adhering to strong ethical principles.

The Public Relations Society of America (PRSA) works with its members to help ensure that practices in the industry are ethical and to provide guidance to members when situations

become ethically questionable. Toward this end, the association provides an extensive Member Code of Ethics for public relations practitioners. This document articulates the value the association places on advocacy, honesty, expertise, independence, loyalty, and fairness. The code also includes specific provisions about the free flow of information, competition, disclosure of information, safeguarding confidences, conflicts of interest, and enhancing the profession. These provisions include guidelines as well as examples of improper conduct under each provision.

Perhaps in anticipation of and response to the stigma of deception that is often used against public relation practitioners, the PRSA Member Code of Ethics ends with a pledge for its members:

To conduct myself professionally, with truth, accuracy, fairness, and responsibility to the public; To improve my individual competence and advance the knowledge and proficiency of the profession through continuing research and education; And to adhere to the articles of the Member Code of Ethics 2000 for the practice of public relations as adopted by the governing Assembly of the Public Relations Society of America.

I understand and accept that there is a consequence for misconduct, up to and including membership revocation.

And, I understand that those who have been or are sanctioned by a government agency or convicted in a court of law of an action that fails to comply with the Code may be barred from membership or expelled from the Society.

## Puffery

While overly representing the characteristic value of an item to be greater than in actuality has its roots deep in human history, the word *puffery* is a relatively new legal term of art. Puffery is most commonly the use of exaggerations reasonably expected from a seller regarding the degree of quality of a product, the truth of which cannot be precisely determined. The exaggerated commendation for promotional purposes must not be material to the true character of the product for fear of leading to fraud or intentional misrepresentation. Puffery, although a specifically protected form of speech under the First Amendment to the U.S. Constitution, remains highly regulated to prevent commercial abuse of unsuspecting consumers. Product puffery is not the sole form promotional praise may take, but rather puffery of individual prowess is commonplace among professional service providers and is often the form most readily abused.

Puffery, although likely used for as long as commercial enterprise has existed, first appeared in legal form in 1893 in the English case of *Louisa Carlill versus the Carbolic Smoke Ball Company*. Following the 1890 influenza pandemic, the Carbolic Smoke Ball Company advertised a product guaranteed by monetary payment to prevent contraction of the virus by a regular user. Louisa Carlill used the product as directed; however, she contracted influenza despite the commercial claims and subsequently filed suit for payment under the advertised guarantee.

The respondent company argued in its defense that its claims that no product user ever contracted

Puffery in advertising is primarily utilized to subtly, and harmlessly, encourage consumers to buy a specific product or engage services from a specific individual. Promotional statements that express subjective rather than objective views to

*A Campbell's Soup ad in the January, 1934, issue of American Magazine promises an "old-fashioned" taste that "everybody likes." Puffery, an over-representation of the characteristic value of an item, became more regulated in commercial use in 1946.*

Although limited formal definitions exist, the “reasonably prudent person” standard is used universally in legal practice as a legal fiction to qualify the expectations and duties of a similarly situated individual. The reasonable person standard attempts to objectify standards that may otherwise appear to be subjective to each individual. Regarding a consumer who relies upon the puffery of a salesman, the standard of what comments become material to the inducement of a sale, rather than merely imprecise promotional exaggerations, may be found in what a consumer

of similar knowledge and expertise would rely upon when comparing a product for purchase. When the reasonable person of similar knowledge and expertise would find that a statement claiming, for instance, a car gets the best gas mileage of any car on the lot forms the basis for purchasing that specific car, the consumer of said car may hold the seller liable for such claims that go beyond mere puffery.

The legality of all claims of exaggeration, or the associated defense that such exaggeration was merely puffery, hinges on that which constitutes protected speech under the First Amendment. Commercial speech by a company or individual is done with intent of making a profit and by its nature proposes a commercial transaction that may be controlled under a variety of trade regulations. Commercial speech is afforded a limited measure of freedom and is not necessarily “free” to be spoken without restraint. The regulation of commercial speech, and consequently puffery, may be imposed where the limitation of what can be stated is founded in an important governmental interest. As commercial enterprise is considered an important interest to the government, statements about a product intending to induce a sale may be appropriately regulated.

Puffery is allowable as speech free from regulation, and thus free from liability upon the part of the speaker, because its immaterial nature cannot be considered by the reasonable person to induce entry into a purchase of product or utilization of service. The lines of distinction for allowable puffery and regulated speech are even more ambiguous when such statements are intended to induce a consumer in the utilization of an individual for professional services, such as the employment of an attorney.

Attorneys must be very careful about the terms and phrases utilized when describing their legal prowess, as lawyers are often held to a higher standard regarding permissible puffery. Statements that a reasonable person may find predictive of an outcome regarding their legal claim go beyond allowable puffery and subject the attorney to sanctions under every state bar association. Exaggeration crosses the line of permissible puffery when claims of superiority or expertise in legal prowess over other attorneys cannot be qualified by sanctioned certification by the governing bar. Likewise,

certain exaggerations go beyond puffery when they constitute commercial speech, such as having never lost a case or a guarantee of success sought to induce the utilization of the specific legal services, and thus are forbidden in legal advertising.

### Nonverbal Advertising

Puffery is readily observable in the nonverbal “advertising” engaged, for example, by an attorney as self-promotion of his or her propensity for success. The luxurious office, the expensive automobile, the lavish personal residence, and even the physical attractiveness of the legal staff all allude to the attorney who is successful. Potential clients associate such indicators with an attorney having a greater probability of prevailing in their interest and so more readily seek out the legal services of that counsel. Puffery in like form is acceptable and forms no basis for fraudulent inducement, as no reasonably prudent person would stake the validity of a legal claim on such indicators of attorney self-promotion.

Puffery has been a major advertising tool since the Industrial Revolution and when used appropriately has been determined to be harmless to the consumer. The U.S. Supreme Court and government agencies allow the use of puffery as free speech under the First Amendment as statements that are immaterial to the product or service and would be relied upon by a reasonable person as the basis of a business transaction. Exaggeration goes beyond mere puffery as deceptive to the consumer and misrepresentative of the product or service sought. Puffery continues to be expected in commercial enterprise and where implemented appropriately exhibits little probability of harm to the average consumer.

# R

## Racism

Racism and other forms of prejudice have increasingly become a topic of interest to social scientists who study deception. This interest largely stems from the observation that blatant and explicit displays of prejudice, which were once commonplace, tend to occur rather infrequently in the modern world. Some have argued that this is evidence of a true decrease in racism over time. In contrast, others have argued that as societies have begun to espouse more egalitarian values, people have simply become less willing to divulge their true racial attitudes in such an obvious way.

Evidence from a variety of sources provides support for the latter view, indicating that modern racism is often intentionally masked in survey research through lies and deceit. Moreover, some people may actually be deceiving themselves about their true feelings when it comes to race. To combat these issues, psychologists have developed techniques for bypassing such deception and detecting implicit racial attitudes. The results of this research have revealed that while racism has become more covert in the present day, it is still very much alive and well despite frequent claims to the contrary.

### Denial of Racism

Although white Americans have historically held negative attitudes toward blacks, survey research

suggested that this bias had effectively disappeared by the end of the 20th century. Study after study found that white participants were rating blacks just as favorably as they did their own racial group. And it is not just white-black prejudice that has seemingly disappeared—most forms of race-based prejudice appear to have been waning in recent years. At the same time this was noted, however, studies looking at the association between race and behavior appeared to indicate that things had not changed one bit: whites were still providing preferential treatment to members of their own race and penalizing racial outgroups. Thus, despite claiming that they are not prejudiced, studies continue to find that whites are treating members of other races differently on everything from whom they would hire for a certain job to the severity of the punishment they would assign to a criminal offender.

As one particularly compelling laboratory example of this seeming duplicity, a classic study by Shirley Weitz found that the white participants who expressed the most favorable attitudes toward blacks on a survey actually demonstrated the least friendliness toward a black confederate in a subsequent interaction. For a real-world example demonstrating similar hypocrisy, consider the case of gubernatorial candidate Tom Bradley, the first African American mayor of Los Angeles, who ran for governor of California in

*The first black mayor of Los Angeles, Tom Bradley (left), meets with Orange County Supervisor Ralph B. Clark in 1980. The Bradley effect is named after his race for governor of California in 1982, when he was ahead in the polls but lost on Election Day. Pollsters theorized that this was a type of social desirability bias, in which voters lied at the polls to avoid appearing racist.*

1982. Although a variety of public opinion polls showed that he held a significant lead going into the election, he wound up losing the race to a white candidate. Although the polls could have been wrong in that instance (just as they were in the infamous Dewey-Truman presidential contest of 1948), pollsters and social scientists have documented a number of other cases since then in which political polls have overestimated support for racial minority candidates. This phenomenon has since been dubbed the “Bradley effect.”

According to psychological research, this apparent disconnect between people’s self-reported racial attitudes and behaviors is mostly a matter of deception. Individuals may intentionally lie about their true racial attitudes when participating in survey research or political polls for any number of reasons. For example, some people may feel compelled to conform to egalitarian social norms, or they may seek to present themselves in the most positive light possible by

expressing a high degree of political correctness. And people do not report just a slight attitude adjustment. For instance, in the case of the aforementioned Weitz study, racist participants actually overcompensated by presenting themselves as the least biased individuals in the entire sample.

Psychologists have found that the pressure to suppress and disguise information about the self that other people might perceive as undesirable (known as the “social-desirability bias”) is incredibly strong. As some evidence of this phenomenon in the arena of race, consider what research on the Bogus Pipeline technique has concluded. In Edward Jones and Harold Sigall’s original study that pioneered this method, they recruited a sample of white individuals who were asked to indicate whether a set of positive and negative attributes was characteristic of African Americans. However, half of the participants were first hooked up to a supposed lie-detector machine via electrodes and were essentially told that the machine could read their minds by measuring their “implicit muscle movements.” In reality, the machine was completely bogus and was not even recording any physiological information; the goal of this elaborate setup was simply to convince participants that they should tell the truth because it will come out one way or another. The other half of the sample never saw or heard about this machine.

The end result was that in the Bogus Pipeline condition, participants rated negative attributes (for example, lazy, ignorant) as more characteristic of African Americans and positive attributes (for example, intelligent, sensitive) as less characteristic of this same race than did participants in the control condition. These results provide strong support for the idea that, under normal circumstances, people tend to lie about their true racial attitudes in order to appear nonprejudiced. It is only when they have an incentive to tell the truth that such bias tends to emerge.

However, active deception is not the only factor at work here. Self-deception may also play a major role. In other words, some people may be hiding their true feelings about race from themselves. This can occur at either a conscious or unconscious level, which means that people may not necessarily realize this is even happening. The reason people engage in such self-deception

regarding their racial attitudes is that deceiving themselves about their own positive attributes and about others' negative attributes may help them to maintain high levels of self-esteem and self-confidence. For instance, if individuals can convince themselves that they are not prejudiced, they are then able to benefit from perceiving the self as moral and just.

As counterintuitive as this may seem, this does not necessarily prevent people from displaying prejudice in the future. When individuals experience situational threats to their self-esteem, they may actively discriminate against minorities as a way of restoring their threatened self-image. Research by Steven Fein and Steven Spencer has found that derogating racial out-groups actually helps people to recover from losses to their self-image. This can occur without necessarily contradicting the overall view of the self as nonprejudiced, because such instances may be selectively ignored or simply not categorized as discrimination because possessing nonprejudiced credentials may effectively license one to engage in discriminatory behavior with impunity.

In short, it would appear that multiple forms of deception are responsible for the paradoxical finding that racism has largely disappeared on attitudinal measures but is still present on behavioral measures.

### **Bypassing Deception in the Study of Racial Attitudes**

The scientific study of racism has become more complicated over the years because lying and deception have substantially increased on explicit measures of prejudice as societies have become more egalitarian. To get around the problems of people being both unwilling (active lying) and unable (self-deception) to report their true racial attitudes, researchers have had to find new ways of assessing racism.

One of the earliest attempts at this involved crafting more subtle survey items, such as those used on the Modern Racism Scale (for example, "discrimination against blacks is no longer a problem" and "blacks have gotten more economically than they deserve"). Such items do indeed help address social desirability concerns to a small extent because people feel less of a need to misrepresent their true feelings when the

survey questions are less blatant. However, such measures do not begin to broach the issue of self-deception, which is subject to less conscious self-control. In order to bypass the biases inherent in self-report studies, researchers have increasingly turned to implicit measures of racism. Implicit measures seek to assess attitudes of which a person may have no conscious awareness but that can still impact individual behavior.

One such measure is the Bona Fide Pipeline technique, which involves the use of priming to assess implicit racial attitudes. The procedure consists of first priming the participant with a photograph of someone from a particular racial group (for example, white, black, Asian, Hispanic). Specifically, the image is shown for a very short amount of time (that is, milliseconds) on a computer screen. The exposure time is actually so short that participants cannot necessarily consciously report what they have seen.

Afterward, participants are given a set of adjectives and are asked to categorize them as having either a positive or negative meaning. The idea is that the individual's true racial attitudes are uncovered by variations in the speed with which he or she categorizes the words after exposure to an image of someone who is either part of the same or of a different racial group. Specifically, prejudice is revealed to the extent that participants are quicker to categorize negative words and slower to categorize positive words after exposure to someone of a different race. In such cases, negative words will be consistent with their implicit attitudes, while positive words will be inconsistent.

Related to this is the Implicit Association Test, which examines how readily people associate specific social groups with positive and negative descriptive terms. Although it sounds similar to the Bona Fide Pipeline in many ways, the difference is that priming is not used in this case. Instead, participants are shown a series of faces and asked to categorize whether they represent the category of black or white. Next, they are presented with a series of words that vary in emotional valence (for example, joy, agony, peace, failure) and are asked to categorize whether they are good or bad. Then participants are asked to complete a combined task in which they categorize both words and faces. However, in this case, each of the racial categories

is paired with one of the attribute categories (that is, black faces and bad words versus white faces and good words, or black faces and good words versus white faces and bad words). The basic idea is that when a subject has a faster and easier time with the categorization task when the racial minority group is paired with negative words rather than with positive words, the subject harbors more implicit prejudice toward that group.

Perhaps not surprisingly, research comparing the results of these implicit measures to data obtained from explicit (that is, survey) measures has revealed that they often do not converge when it comes to racial attitudes, suggesting that they are indeed measuring different things. That said, both the Bona Fide Pipeline and Implicit Association Test have been criticized on the grounds that perhaps they simply capture participants' knowledge of broader cultural and societal stereotypes of racial minority groups, meaning they may not necessarily reflect participants' true attitudes. However, studies have shown that scores on each of these tests do indeed predict subsequent expressions of prejudiced behavior toward targets of different racial categories.

For instance, greater levels of implicit racial bias predict displaying less friendliness and taking a seat further away from a racial minority member during an interracial interaction. Moreover, implicit attitudes tend to be an even stronger predictor of discriminatory behavior than explicit, self-reported racial attitudes. This finding lends further support to the idea that the predictive validity of explicit racism measures is compromised by deceptive reporting on the part of participants. Studies have also found that implicit procedures, such as the Bona Fide Pipeline and Implicit Assumption Test, are relatively resistant to social desirability biases, and that intentional deception, while technically possible, is relatively rare and especially difficult for people who are new and unpracticed at these tasks. Thus, the overall body of research in this area indicates that there may actually be a number of ways to break through both intentional lying and self-deception in the study of racism.

### Conclusion

In short, although some studies suggest that racism has decreased over the past few decades, it

appears that this "decrease" is most likely just an artifact of widespread deception in how people respond to explicit measures of racial bias. Such deception can be the result of intentional lying, as well as subtle forms of self-deception. However, measures of implicit racial attitudes, such as the Bona Fide Pipeline and the Implicit Association Test, appear to bypass both conscious and unconscious deception and may perhaps provide a more accurate gauge of individuals' true racial attitudes.

## Rationality

Rationality is a characteristic of belief, action, and decision. It is generally described as having the following aspects:

- *Reasoned justification.* When one's beliefs, actions, or decisions are rational, one should be justified in his or her reasons or goals.
- *Conformity.* When one has a goal or a problem to be solved, one's rational beliefs, actions, or decisions should conform to the goal or the solution.
- *Consistency.* When one derives rational beliefs, actions, or decisions from a goal or a problem to be solved, those beliefs, actions, and decisions should be consistent across cases, situations, or contexts.
- *Optimality.* When one has a rational belief, takes a rational action, or makes a rational decision, the belief, action, or decision is optimal for the goal or solution among other possible alternatives.

The term *rationality* is used differently or in more specific ways in different fields of social science. The fields of psychology and behavioral economics have studied the relationship between deception and rationality.

*Homo economicus.* Psychological studies that focus on judgment and decision making have treated the concept of rationality from two points of view: the normative microeconomics model and the descriptive model of human behavior.

In the normative microeconomics model, rationality refers to the characteristics of behavior in

*Homo economicus*, or economic man. This concept maintains that human beings are rational and narrowly self-interested actors who egocentrically pursue material desires. These characteristics are based on the following principles of *Homo economicus*'s behavior: He pursues only self-interest; he always seeks optimal behavior that maximizes self-centered, material gains; and his decisions, which are based on the maximization of selfish material gain, are consistent across contexts.

These principles imply that *Homo economicus* has a means to evaluate utility for behavioral options. Utility for *Homo economicus* is based only on the context-free, ordinal, and measurable materialistic aspects of material gains and losses. The principles also imply that *Homo economicus* is capable of immediate and precise calculations of the utility in any situation. However, the principles of *Homo economicus* (that is, the normative microeconomics model) are not always compatible with actual human behavior. Psychologists' studies of human behavior in judgment and decision making have found many cases in which people violate the following principles:

*Reversal of preference.* When *Homo economicus* chooses an option, the option is optimal at any time. But people often reverse their preference, such as preferring to get \$100 immediately rather than \$200 one year later. However, people always prefer to receive \$200 over \$100 if they can get either amount immediately.

*Mental accounting.* When *Homo economicus* calculates outcomes of choice, the total gain or cost is constant. In practice, however, people mentally frame assets such as current income, current wealth, or future income. This implies that in human behavior, the accounts are not fungible, and the marginal propensity to consume out of each account is different.

*Refusal in ultimatum game.* In an ultimatum game, two players divide an amount of money between them. One player has the right to decide how to divide the sum, but another player can turn down the proposal if he or she doesn't like the offer. In case of refusal, the pay-off to both players is zero. If the second player is *Homo economicus*, he should accept the first player's offer

as long as it is not zero, because the offer is better than zero payment in case of refusal. In experiments, however, people tend to turn down the first player's offer when they feel it is unfair, that is, they are willing to accept zero payment.

*Altruistic punishment in public goods game with punishment rule.* In a public goods game with a punishment rule, multiple players decide for themselves how much to invest in a share of the sum in a pot. Money put into the pot is multiplied by a certain factor (commonly 1.4 to 1.6) and paid out in equal shares to all players. After one round of the game, players can make another kind of investment to punish a player who made zero investment in the first round. A *Homo economicus* would not commit such a punishment at his personal cost, because he never benefits from punishment. In experiments, however, people tend to invest to punish players who are free riding.

If seen from the classical microeconomics' point of view, actual human behaviors are far from rational. Herbert Simon explained this discrepancy, pointing out that it is impossible for real people to achieve normative rationality because their cognitive ability is too bounded to make optimal choices that maximize ordinal and measurable utility. Instead, he offered the alternative idea that people are still rational in the sense that they try to achieve a satisfying choice with their limited cognitive ability. This idea, called "bounded rationality," is now advocated by a new group of economists, as well as psychologists. By means of empirical methods, these economists have created the new field of behavioral economics in order to pursue a descriptive model of realistic human behavior. Thus, psychologists and behavioral economists have developed their theoretical positions in a similar way.

### Rationality in Studies of Deception

Deception is sometimes studied in relation to rationality. Similar to studies on judgment and decision making, behavioral economists have researched deceptive behavior by using a normative economic model of crime, which refers to the traditional sense of economic rationality.

An example of the normative economic model related to deception is Gary Becker's Simple Model of Rational Crime (SMORC). It suggests

that people commit crimes on the basis of a cost-benefit calculation: People compare the cost and benefit from both positive and negative outcomes of a crime. If the total benefit exceeds the total cost, they will commit a crime; in the context of deception, they will tell the truth if being honest is more beneficial.

In recent years, however, psychologists and behavioral economists have reported findings suggesting that human deception does not follow the normative economic model. For example, Uri Gneezy investigated how people responded to monetary incentives when there were no economic costs to deception, no risk of detection, and no punishment for detection. He created a Sender-Receiver game in which only the sender was aware of the payoffs for the two options available: one option paid him more money than the receiver, while the other option paid the receiver more. The sender was free to deceive the receiver in order to receive a higher pay-off, and he could do so without risk because the experiment prevented the receiver from knowing the truth, even after the payment had been made.

Gneezy's finding was that not all the senders lied. More significantly, he also found that, when faced with a large difference between the payout options for the receiver (that is, the receiver's loss was large), less than 20 percent of the senders lied. This result suggests that the target's loss can be considered a type of cost that discourages potential liars. This finding goes against the normative economics principle of egocentricity and contradicts the SMORC model, which predicts that, as rational actors, senders would always tell their receivers a lie.

In the same study, Gneezy also compared the sender-receiver game to the dictator game, in which one player (the dictator) not only knows the payment for each option but also decides the action. The dictator was allowed to keep the payment for the other option he or she did not choose. Note that in the dictator game, no lying could be involved. Applying the same pay-off conditions, Gneezy found that most dictator-players picked the option that benefited the dictator themselves, while fewer senders lied in the same pay-off condition of the sender-receiver game. This difference suggests that people do not calculate economic cost and benefit in a consistent way: in terms of

the economic cost and benefit, these two games were the same, which suggests that the games cause the same percentage of lying, but this was not the case. Again, the result contradicts the normative economics theory.

Gary Charness and Martin Dufwenberg reported another violation of normative economics principles using a trust game between two players. In the game, player A has two options: Let player B make the decision (the option “In”), or choose a less attractive payment for both A and B (the option “Out”). Player B can choose only if A takes “In; he can choose the option “Don’t roll,” which guarantees him the greater pay out, or the “Roll” option, which benefits him less, but might benefit A more than A’s “Out” option.

In this game, researchers found that when player B verbally promised to choose the option that benefits player A (that is, “Roll”), and A allowed B to make the choice (that is, “In”), fewer people in the player B role chose the selfish option of “don’t roll.” Charness and Dufwenberg explained this effect with a theory of guilt aversion: people felt guilty to the extent that they believed they were hurting the other party. In other words, people were motivated by their beliefs about others’ beliefs. Charness and Dufwenberg also suggested that guilt aversion prevents people from deceiving others even when deception benefits them.

In his book *The (Honest) Truth About Dishonesty*, Dan Ariely introduced many other examples of human dishonest behavior that contradict the normative economic principles of rationality (this is SMORC). He found that the effect of economic cost-benefit calculations was weaker than psychological factors. Dishonesty decreased with moral reminders but increased with factors irrelevant to economics, such as cognitive fatigue, creativity, others benefitting from someone’s dishonesty, and watching others behave dishonestly.

Ariely arrived at an alternative rational theory of human dishonest behavior. When faced with situations in which dishonesty is an option, people are affected by two conflicting motivations: the rational economic motivation and the psychological motivation to view themselves as morally sound human beings. People sought to satisfy both motivations at the same time by cheating in a subtle way that does not hurt their positive self-image. Ariely implied that this kind

of self-justification reflected another kind of rationality for flexible human beings: People seek to satisfy multiple and conflicting goals.

## Conclusion

The concept of rationality has provided normative hypotheses on human behavior and has helped psychologists and behavioral economists discover significant findings on the nature of human behavior, including deception. Researchers also have elaborated on the concept of rationality so that it fits the reality of human behavior.

# Reaction Time

Attempts to diagnose deception using reaction time (RT) date back at least a century. In 1920, William M. Marston—better known as a pioneer of the polygraph—investigated with a stopwatch whether the honest or dishonest reporting of data from printed cards produced faster or slower RTs. In recent decades, advances in chronometry and computing have made the accurate and affordable measurement of RT ever easier. Accordingly, many contemporary researchers have explored

afresh the diagnostic potential of RT. The result has been the development of several promising and efficient lie detection techniques.

### **Rationale**

Why should RT diagnose deception? Everything else being equal, the more complex a mental process is, the longer it takes to unfold. In general, lying is a more complex process than truth-telling. Hence, lying takes longer to unfold. It follows that RT can empirically distinguish lying from truth-telling.

Why is lying a more complex process? There are several reasons. For one thing, lying involves extra cognitive operations. In an honest respondent, an inquiry automatically activates knowledge, which is then directly communicated. In a dishonest respondent, however, knowledge activation is followed by deliberation over whether to tell a lie, and once the decision is made, by an attempt to construct one, entailing the suppression of activated knowledge and its replacement by an appropriate fiction. Moreover, the ongoing challenges of keeping a false narrative straight, of monitoring and managing one's demeanor, and of dealing with the fear of exposure all compound the complexity of lying.

The greater complexity of lying makes it more difficult. Hence, for lying to succeed, relatively more mental effort must be exerted and relatively more mental resources must be available. Tellingly, slower RTs are often accompanied by increased errors. Note that, given the speed-accuracy trade-off, attempts to reduce errors will retard RTs, while attempts to hasten RTs will increase errors.

### **Measurement, Magnification, Manufacture, and Modification Detection Techniques**

RT-based lie detection techniques can be grouped into four classes. Those in the first class involve measurement. They simply capitalize on lying being naturally more complex than truth-telling. Those in the second involve magnification. They amplify the foregoing natural difference. Those in the third involve manufacture. They engineer an entirely artificial situation in which slower RTs diagnose deception. Those in the fourth involve modification. They take an existing paradigm and add RT measurements to it.

On occasion, techniques in all classes detect deception comparatively well. The jury is still out, however, on whether they will ultimately prove robust to countermeasures or practical to implement. The techniques are described as follows:

*Measurement.* When respondents lie, their verbal replies to spontaneous inquiries take longer. Yet this effect seems confined to inquiries that arouse emotion; plain facts can be lied about just as quickly. However, if verbal inquiries are repeated and verbal responses to them dichotomized (for example, as yes/no), or if statements are presented on a computer for digital classification, then the effect emerges solidly for plain facts too. True, prior practice at lying, by decreasing RTs generally, attenuates diagnostic accuracy. However, taking errors into account alongside RT augments accuracy.

*Magnification.* If lying is cognitively more complex, but truth-telling is cognitively simpler, then the imposition of a concurrent mental load should interfere more with lying than with truth-telling. This should, despite inducing an overall slowing, amplify differential effects on RT. Sure enough, if liars relate a series of fictitious events backward—something that heavily depletes processing resources—they then speak more slowly and hesitate more often, an effect not observed if they relate that series of events forward. Moreover, observers are better at distinguishing liars from truth-tellers if liars are kept mentally busy by being forced to maintain eye contact, possibly because observers notice, among other things, some revealing increases in RT.

*Manufacture.* In the Timed Antagonistic Response Alethiometer (TARA), respondents rapidly classify statements as true or false by pressing one computer key or another. Crucially, they alternately co-classify two different types of statements: target statements, which are empirically true or false and which may be classified either honestly or dishonestly; and control statements, which are analytically true or false, and which must be classified accurately. Truth-tellers now have an advantage: They can use the same strategy to classify both target and control statements (for example, “p” for all true statements, “q” for all false statements). Liars, in contrast, must use

one strategy to classify target statements (for example, “q” for true and “p” for false), and another to classify control statements (for example, “q” for true and “p” for false), and keep switching between them. Lying is thus made more difficult than truth-telling. Accordingly, liars exhibit longer average RTs than truth-tellers.

A cousin of the TARA is the Autobiographical Implicit Association Test (AIAT). Here, target statements take the form of accusatory or defensive statements, which respondents respectively classify as “guilty” or “innocent.” In one block, control and target statements get co-classified as true/innocent or false/guilty. In another block, they get co-classified as true/guilty or false/innocent. Slower RTs in the former block—driven by incriminating semantic associations—diagnose deception.

*Modification.* The Concealed Information Test (CIT)—a more general version of the Guilty

Knowledge Test (GKT)—works by detecting an orienting response toward selected items that only a guilty liar would recognize. In contrast, an innocent truth-teller, not recognizing any of the items, should not consistently orient toward any item. Traditionally, the orienting response has been operationalized physiologically—most commonly as a peak in skin conductance. However, RT can be readily substituted, or added as an ancillary index.

Respondents completing RT-based CITs classify three types of items: those familiar to everyone, those familiar to liars, and those unfamiliar to everyone. Both truth-tellers and liars accurately affirm recognition of the first type of item and accurately deny recognition of the third type of item. However, whereas truth-tellers honestly deny recognition of the second type of item, liars dishonestly deny it. These dishonest denials take longer than honest denials, permitting liars and

*Observers are better at distinguishing liars from truth-tellers if liars are kept mentally busy with forced, maintained eye contact, possibly because observers notice increases in reaction time. If liars are made to relate a series of fictitious events backward—something that heavily depletes processing resources—they then speak more slowly and hesitate more often than if they were telling the truth.*

truth-tellers to be distinguished. Combining RT with physiological indices also augments diagnostic accuracy.

## Reality Monitoring

Sometimes a question arises as to whether someone actually experienced an event or whether the memory they have of it in their mind is based on imagination. The processes by which a person attributes a memory to an actual experience (external

source) or imagination (internal source) is called reality monitoring. Although the reality monitoring (RM) concept is not related to deception, scholars believe that the concept has this application and can be used as a lie detection tool. Much of the RM deception research is concerned with testing the assumption that RM assessments can be used to discriminate between truth-tellers and liars.

The core of RM is that memories based on real experiences differ in quality from memories based on fiction. In their seminal work on memory characteristics, Marcia Johnson and Carol Raye argued that memories of real experiences are obtained through perceptual processes. These memories are therefore likely to contain (1) sensory information: details of smell, taste or touch, visual details, and details of sound; (2) contextual information: spatial details (details about where the event took place, and details about how objects and people were situated in relation to each other), and temporal details (details about the time order and duration of events) and (3) affective information: details about people's feelings throughout the event. These memories are usually clear, sharp, and vivid.

By contrast, memories about imagined events are derived from an internal source and are therefore likely to contain cognitive operations, such as thoughts and reasoning ("I must have had my coat on, as it was very cold that night"). These are usually vaguer and less concrete.

### Reality Monitoring and Lie Detection

Scholars since 1990 have examined whether RM analyses can be used to discriminate between truths and lies. The assumption these scholars make is that truths are recollections of experienced events, whereas lies are recollections of imagined events. Obviously not all lies are descriptions of events that a person did not experience. Many lies are not about events but are about people's feelings, opinions, or attitudes. And even when people lie about events (about their actions and whereabouts), they can sometimes describe events that they have actually experienced but at a different time. For example, a burglar who denies having committed a burglary last night can claim that he went to the gym instead. He can then truthfully describe a visit he made to the gym but which he made on another occasion.

Researchers have examined whether deceptive statements that are based on events that the liar imagined differ in terms of RM criteria from truthful statements about experienced events. The typical procedure in these studies is that liars and truth-tellers are interviewed, and these interviews are taped and transcribed. RM experts check for the presence of RM criteria in these transcripts. A standardized set of RM deception criteria has not been developed to date. Different researchers use different criteria and sometimes use different definitions for the same criterion.

Most researchers include the following criteria in their RM veracity assessment tool:

*Clarity and vividness of the statement.* This criterion is present if the report is clear, sharp and vivid instead of dim and vague.

*Perceptual information.* This criterion refers to the presence of sensory information in a statement, such as sounds (“He really shouted at me”), smells (“It had a smell of rotten fish”), tastes (“The chips were very salty”), physical sensations (“It really hurt”), and visual details (“I saw the nurse entering the ward”).

*Spatial information.* This criterion refers to information about locations (“It was in a park”) or the spatial arrangement of people and/or objects (“The man was sitting to the left of his wife”).

*Temporal information.* This criterion refers to information about when the event happened (“It was early in the morning”) or explicitly describes a sequence of events (“When he heard all that noise, the visitor became nervous and left”).

*Cognitive operations.* This criterion refers to descriptions of inferences made by the participant at the time of the event (“It appeared to me that she didn’t know the layout of the building”) or inferences/opinions made when describing the event (“She looked smart”).

All criteria are thought to be more present in truthful than in deceptive accounts, except the cognitive operations criterion, which is thought to be present more in deceptive than in truthful accounts. Research has shown general support for

these assumptions, although the support for some criteria, such as temporal and spatial details, is stronger than the support for other criteria, such as cognitive operations. Moreover, truths and lies can be detected above the level of chance with the RM tool, with average truth and lie accuracy scores being just below 70 percent.

There are restrictions in using an RM veracity assessment tool. For example, the tool cannot be used with young children. In some circumstances children do not differentiate between fact and fantasy as clearly as adults do, for several reasons, including that children have a richer imagination than adults. Children may therefore be better than adults at imagining themselves performing acts.

It is probably also difficult to use the RM tool when people talk about events that happened a long time ago. Over time, cognitive operations may develop in memories of experienced events because they facilitate the remembering of events. Someone who drove fast in a foreign country may try to remember this by remembering the actual speed his speedometer indicated; alternatively, he could remember by logical reasoning and by deducing that he must have driven fast because he drove on the motorway. Imagined memories, on the other hand, can become more vivid and concrete over time if people try to visualize what might have happened.

## Conclusion

Reality monitoring refers to the process by which a person attributes a memory to an actual experience (external source) or imagination (internal source). Although the RM concept is not related to deception, it could be applied to deceptive contexts when liars discuss an event that they have imagined rather than experienced. In such situations RM can discriminate between truths and lies at just below 70 percent accuracy. RM cannot be used with very young children or when people talk about events that happened a long time ago.

## Relationships: Family

Lying among family members is a complex topic to explore, primarily because of the complex nature of the definition of family structures in general. Additionally, lying within families can be a complex concept to consider because it is often considered a "natural" process, especially when considering the development of children and adolescents in families. The conclusions from this research are numerous. First, studying or defining lying in family units is a complex analysis to draw. Second, lying for different groups of family members has different sets of repercussions. For example, lies told by children are thought to be (to a degree) a natural component of maturation. However, the way lying is viewed changes greatly from childhood to adolescence to adulthood. Each developmental stage is accompanied by its own set of expectations related to lying and deception. Finally, lie-telling in children is thought to be a critical component of their social-cognitive development.

Much more research is needed in the specific areas of lying and deception in nontraditional

and non-nuclear families, such as extended families, parents with adopted children, homosexual couples and their children, and blended families (including stepchildren and half siblings,). Furthermore, more study is needed to address lying norms among siblings, as well as among parents and their children.

The definition of the makeup of a family unit was originally much more concrete than it is today. The traditional definition of a family was a heterosexual, married couple and any biological children that they had together. That definition has since broadened to include heterosexual couples with no children, homosexual couples, foster parents and their foster children, stepchildren, and blended families, among others. Also included are parents who have adopted children, and in some cases even close friend networks are considered family units. With this premise in mind, detecting deception among family relationships can be a complex process.

Three types of lies are prevalent in research on deception and lying: (1) lies to harm others, (2) lies to protect the self, and (3) lies to spare others. Research has been done on lying in television families, and reports show that lies to spare others are the most common types of lies depicted in these families, with the husband/father characters lying the most, the children depicted as the most honest characters, and the majority of lies undetected. More important, researchers argue that these conclusions about television families run parallel to real families. Thus, in actual family units perhaps lies with the purpose of sparing others are in fact the most commonly told. More research needs to be conducted in this area, particularly to determine if this conclusion is valid and, if so, how the patterns among family members relate to patterns in nonfamily groups.

### Parents Teaching Children About Lying

Parents are typically considered the people who are responsible for teaching their children right from wrong, which is deemed part of the normal socialization process. However, it is assumed that there will be some bumps in this instruction, and that correcting those missteps is the way to teach fundamental, moral principles. It is expected that children and/or adolescents will lie to their parents at some point. It is also assumed that parents will

correct this behavior and thus, lying is deemed an immoral behavior. Lying is an action that will often result in punishment in a household.

However, studies on moral development and lying behavior show that children are also taught that lying, in some cases can be seen as acceptable. For example, if a child is asked by a friend if he or she likes the friend's coat, parents teach their children that it is considered to be polite to be a little dishonest. Thus, this process of learning to differentiate right and wrong when it comes to lying can be a complex one.

Also, adolescents face decisions regarding deception, and parents face a new set of challenges when dealing with disciplining or instructing them about the issue. Adolescence is often the time when children will choose to initiate independence from their parents. This can take many forms, but often the question of honesty arises in some vein. The issue of deception among adolescents (and the involvement of their parents) is a complex one because many believe that the openness of the communication environment that parents create in the home has direct impact on whether or not an adolescent will choose to lie or be deceitful. Others believe that the more open a communication environment in the home is, the more freedom adolescents feel to communicate how they choose. Some feel that open communication and firm, strict discipline cannot work together and if parents are too open in their communication with their adolescents, the teens will begin to perceive the openness as a window to make their own poor choices, independent of their parents' wishes or discipline.

Families that have experienced divorce are a rising population, and parents who choose to divorce face a unique set of challenges when it comes to honesty about the situation. Studies have shown, however, that there are strong correlations between whether or not a child feels that he or she was being deceived in the communication about the divorce and the child's overall level of communication satisfaction with their parent. There can be many negative impacts of divorce for children. Some children may have lower self-esteem or a difficulty in developing socially. Studies do show, though, that the way that parents communicate with their children about the divorce can impact the intensity of these repercussions. A

study conducted by Candice E. Thomas, Melanie Booth-Butterfield, and Steve Booth-Butterfield found that children who report feeling deceived in the communication they receive from their parents about an impending divorce feel less satisfied with their communication with their mothers.

### Family Secrecy

Family secrecy is another interesting topic to consider when discussing deception among family members. At times, families have certain rules or norms that are often unspoken but understood. These rules might relate to verbal communication (for example, "children should never speak unless they are spoken to by an adult or initiate conversation as such"), behavior (for example, "our family is always on time"), or emotions (for example, "our family does not openly display negative emotions in public").

Rules about secrecy often apply in family units. Kathleen Galvin and Bernard Brommel state that, "Secrets create or reinforce boundaries—whether between the family and the outside world or around individuals or subsystems." Thus, some secrets may be known to the entire family but not to the outside world, or some secrets may be known only to certain members of the family (intrafamily secrets), or known only to an individual family member (individual secrets). Although lying, being deceitful, and withholding information from others (secret-keeping) are typically thought of as negative constructs, secrecy, in this sense, can have some positive outcomes for the family unit. Sometimes keeping secrets within a family unit can reinforce family identity or a sense of cohesion among the group. For example, if one member is embarrassed by something in particular and the family agrees not to share that information with anyone outside the family, it can make that individual feel cared for and protected. Additionally, simply knowing that there is information that no one else but one's family members know, whether embarrassing information or not, can make a person feel close to his or her family and solidify feelings of solidarity with their family members.

There are, of course, different types of family secrets. Some types, such as those that are in fun, for a surprise, or promote boundaries that are necessary and enhance feelings of solidarity

or comfort, can have positive impacts on the family unit and its relationships. Other types of secrets may have mild to severe consequences for individual family members or the overall family unit. For example, lying (or withholding information) about an affair or dangerous addiction may severely impair the communication climate within the family. Even more dangerous are types of secrets that could put a family member in immediate danger, such as keeping secrets about sexual, physical, or emotional abuse. Thus, the type of secrecy involved in familial interactions can greatly affect the overall communication climate among family members. Secrets can be positive in that they achieve positive boundaries and redefine relationships and closeness, but secrecy among family members can also be detrimental to individual members and/or the family as a whole. The hinge point in this question primarily depends on the function and purpose of the secrecy.

Additionally, secrecy among families may not solely exist for the present family unit. Secrets are frequently passed down through multiple generations and, again, this can have positive or negative ramifications for families depending on the type of secrecy and the purpose in keeping the secret. Perhaps more important than the actual secrets themselves, patterns involved in secret-keeping among families can be passed down through generations as well. Thus, secret-keeping and the motivations behind it can be a learned behavior that spans generations and affects the communication climate of each family unit along the generational line.

## Relationships: Friends

Friendships play a crucial role in the lives of most people. However, when young adults were asked to describe an experience in which someone hurt their feelings, the most commonly described experience was being hurt by a close friend. Hurt feelings in friendships often result from situations in which one friend communicates a hurtful but honest message. Lies—particularly lies told to spare a friend's feelings—may play an important role in the maintenance of friendships.

According to studies in which people recorded information about every social interaction they had over a period of a week, people lie at least once per day on average. However, people lie less frequently to those people who are closest to them. Researchers have found that people lie in 21 to 27 percent of their interactions with friends, whereas they lie in 35 to 48 percent of their interactions with acquaintances and strangers. In another study, people reported telling approximately two lies per week to their best friend.

### Lies Told To Friends

The types of lies people tell to their friends tend to differ from the types of lies people tell to acquaintances or strangers. In friendships, people are more likely to tell altruistic lies (that is, lies told to spare a friend's feelings or to enhance a friend's well-being) than self-centered lies (that is, lies told to spare one's own feelings or to make oneself look better). In acquaintanceships and in interactions between strangers, the reverse is true. Friends who tell more altruistic lies have higher ratings of closeness and relationship satisfaction than do friends who tell more self-centered lies.

People often lie to friends when telling the truth would involve violating their friends' expectations or impressions. Lies involving intrasexual rivalry fall into this category. In a study in which participants described lies told to friends, the second most common type of lies (following altruistic lies) were lies about intrasexual rivalry (for example, interest in the same potential mate, or even mate poaching). Because people are frequently similar to their friends, there is the potential for mate competition with friends. Fifty percent of people report some degree of intrasexual rivalry with their friends.

The third most common types of lies in friendships were lies about sexual experience and promiscuity. Women were particularly likely to lie to their friends about their own sexual experience, perhaps in part because some women report that they dislike being friends with promiscuous women, whom they may see as potential rivals.

Of course, some lies are told to friends simply to avoid conflict and unpleasantness. People commonly lie to friends when they don't want to comply with a friend's request. For example, one might pretend to have carried out a friend's request when in fact one did not do so, or one might make a false excuse regarding why one does not want to comply with the request.

While it is true that people lie less frequently—and usually with more altruistic motives—to their friends than to strangers, the lies individuals tell to friends tend to be more serious. Most lies to acquaintances and strangers are relatively inconsequential; people usually do not ruminate over or feel guilty about these lies. However, when people are asked to recount the most serious lie

they have ever told—as well as the most serious lie ever told to them—they generally recount lies with close relationship partners (that is, friends, romantic partners, and family members).

### Social Acceptability of Lying to Friends

How socially acceptable (or unacceptable) is it to lie to a friend? Although people generally think it is less acceptable to lie to friends than to strangers, and they feel more discomfort when they lie to close friends, there are certain types of lies that are considered acceptable and useful within friendships. Cross-cultural research in the United States and China has shown that people feel it is acceptable to lie to their friends when those lies serve to protect their friend's feelings, promote affiliation, benefit their friend, preserve privacy, or avoid conflict within the relationship.

Furthermore, people who lie in the service of helping their friends make a positive impression on a potential suitor are considered particularly likeable. Although women are especially likely to lie to protect their friends' feelings, they are more likely than men to think lying is unacceptable in close relationships. Compared to men, women report that past lies told to them were more significant, women are more likely to be upset by the lies, and women are more likely to feel guilty about telling lies in close relationships.

### Detecting a Friend's Lie

Several factors influence how upset people will be when they discover that their friend has lied to them. The closer the friendship, the more important the lie, and the greater the importance one attaches to lying generally, the more upset one will be about the lie. The perceived importance of the deceptive information is the strongest predictor of termination of a close relationship. In one cross-cultural study conducted in the United States and Russia, participants believed that serious lies of omission (such as neglecting to tell a friend that his or her romantic partner has been unfaithful) would be such a serious friendship violation that they would end the friendship.

Of course, people are upset by friends' lies if they realize they have been lied to. People are notoriously unskilled at detecting lies; whether they are any better at lie detection in friendships is a topic of some debate. When people are given

*Circle of truth or web of deception? Research has shown that people lie less frequently to others closest to them. The rate of lying is 21 to 27 percent of interactions with friends, whereas people lie in 35 to 48 percent of their interactions with acquaintances and strangers. However, when people are asked about the most serious lie in their memory, they generally recount lies with close relationships.*

feedback regarding the deceptive cues for a particular sender, they improve at detecting lies told by that particular sender. This would seem to imply that relationship experiences improve one's ability to detect lies within that relationship; however, such improvement may be contingent on receiving accurate feedback. If one fails to detect a friend's lie, one essentially receives false feedback because any deceptive cues displayed by the friend are perceived as truthful.

Counterintuitive though it may be, the ability to detect lies may not be an inevitable concomitant of relationship familiarity. Across a variety of experimental paradigms, there is no unqualified support for the notion that friends are uniformly better (or worse) than strangers at detecting each other's lies. Likewise, there is no firm evidence that people are any better or worse across the board at detecting a friend's lies than a spouse's lies. However, there is some evidence that close friends are more accurate at detecting lies than less close friends, and close friends

are especially likely to improve in their lie detection accuracy during the first few months of friendship.

An important impediment to friends' ability to detect each other's deception may be the truth bias; people generally have a greater bias to interpret communications as truthful for friends than for strangers. Researchers have diminished the truth bias by encouraging judges to be highly suspicious. However, one model of relationship closeness posits that when individuals are close to each other, they will be subconsciously motivated toward "empathic inaccuracy" when they encounter information that is potentially threatening to the relationship. In these instances, it may be better for the friendship for lies to go unnoticed. One study found that close friends were worse than less close friends at correctly judging concealed anger and sadness, emotions which could threaten a relationship.

Most studies of deception detection involve videotaped senders telling lies and truths, along

with judges who watch these videotapes. But some researchers have questioned how externally valid this paradigm is. In real life, people often rely on sources such as conflicting evidence and gossip from third parties to detect lies. In this sense, friends should have a clear advantage over acquaintances and strangers because their relationships would more frequently allow them access to evidence and gossip. Furthermore, to the extent that friends do have an advantage, it may be due to the fact that people judge behavior that looks “different from the norm” as deceptive—and friends have a better idea of the sender’s “norm.”

Could people be aware that something is “off” when they hear a lie, without realizing that their fishy feeling is indicative of a lie? There is evidence to indicate that such “implicit deception detection” occurs in friendships. In one study, both friends and strangers felt less comfortable, less confident, less informed, and more suspicious when they heard a lie rather than a truth—even when they could not identify the communication explicitly as a lie.

Most studies comparing friends’ deception detection ability to that of strangers, acquaintances, and romantic partners have focused on the skill (or lack of skill) of the judges. Equally important, however, is the question of whether senders lie differently to friends than to other people. One study found that people exhibit more arousal and negative affect when lying to strangers than when lying to friends. People may also lie differently to closer friends versus less close friends. Women report planning their lies told to close friends more carefully than their lies told to casual friends; men plan their lies to casual friends more carefully than their lies to close friends.

## Conclusion

Individuals lie less frequently, more altruistically, and about more serious topics to friends than to acquaintances and strangers. People are most upset by lies told by closer friends and by lies perceived as important. Women are more likely than men to be upset by lies in friendships. However, lies told to friends may serve to avoid conflict and maintain the friendship. Although closeness may improve lie detection accuracy among friends,

close friends may also be motivated not to recognize lies that might threaten their friendship if discovered.

## Relationships: Romantic

Deception is widely defined as the intentional manipulation of information so as to instill a false belief within a recipient. Deception within romantic relationships involves deceiving a person one counts as a romantic love interest or partner.

The late scholar Gerald (G. R.) Miller argued that three aspects of romantic involvements should combine to make deception in such relationships both unique and potentially volatile. First, romantic partners share an intimate personal history. This affords them a broad and deep information base about each other—creating both the potential for enhanced detection (through noting inconsistencies between what partners say in the current context versus past knowledge of partners' true beliefs and experiences) as well as exploitation of this information as the basis for deceiving (that is, knowledge of what makes a partner suspicious, and what one can and cannot say in order to be believed).

Romantic partners also share a great deal of time together. Frequent interaction allows for both the possibility of deception as well as opportunity for questioning that leads to detection. Finally, romantic partners often share an intense emotional bond. This amplifies the personal and relationship outcomes associated with honesty and deception, in paradoxical ways. On one hand, partners involved in such relationships are compelled to lie in order to protect partners' feelings and maintain relationship harmony—both of which are exceedingly important in romantic involvements. On the other hand, if/when such lies are discovered the reaction should be intense and traumatic.

### Studies of Deception in Romantic Relationships

Scientific examinations of deception in relationships bear out the reasoning of Miller, especially with regard to the frequency and importance of lying. For example, Ronnie Turner and his colleagues had relationship partners record self-judged "important" conversations and then self-analyze the percentage of statements that were "less than honest." Turner found that fully 61.5 percent of statements in important relationship conversations were judged by the people who defined them as "less than honest." But rather

than viewing this ubiquitous dishonesty as problematic, participants in Turner's study defended it, arguing that fidelity to the maintenance of a close relationship trumps unbridled truth in terms of aiding and enhancing intimacy.

In a similar fashion, Sandra Metts and Helen Chronis examined the types and motives of deception for friends, dating partners, engaged couples, and spouses. They found that the most common reasons people involved in romantic relationships cited for lying were to protect partners' feelings and maintain their relationship.

Perhaps the most detailed examination to date of motives for romantic deception is the work of Susan Boon and Beverly McLeod. When participants in their study were asked whether "complete honesty" was important for maintaining a romantic relationship, only 27 percent of their sample said yes; the vast majority said that "it depends on the situation." In addition, fully two-thirds of their respondents agreed that deception is defensible, especially within situations in which partners' feelings, esteem, or the survival of the relationship are at stake.

### Lie Detection in Romantic Relationships

Given the widespread occurrence and support for deception in romantic relationships, can partners involved in such unions detect each other's lies? Intuition would say yes: a common belief is that people can detect the lies of their loved ones with greater accuracy than those of strangers.

Science, on the other hand, would say no. Researchers Steven McCornack and Malcolm Parks examined the deception detection abilities of romantic couples. They found that increases in romantic intimacy led partners to believe that they could, in fact, detect their partners' lies (that is, confidence in detection ability). At the same time, this increase in confidence was associated directly with an increased belief that the "partner is always telling me the truth," which McCornack and Parks labeled "truth bias." Truth bias, in turn, was directly negatively related to accuracy in detecting deception. That is, individuals involved in romantic relationships believe that they can detect their partners' lies, believe that their partners never lie to them, and are decidedly poor in actual deception detection accuracy. This causal string is known as the McCornack-Parks Model.

But Gerald Miller's reasoning also suggests that when lies are discovered in romantic relationships, the effects should be devastating. The first study to focus exclusively on reactions to discovered deception was the work of Steven McCornack and Timothy Levine. Drawing upon Ellen Berscheid's theory of emotion, as well as prior work in cognition and relational deception, McCornack and Levine argued that relational intimacy, the importance of the information that is lied about, suspicion, and the degree to which lying itself is viewed as a transgression should all impact emotional reactions to discovered deception.

Analyzing the self-reports of several hundred respondents, McCornack and Levine found confirmation for their predictions. They also examined the impact of these variables upon relationship termination. They found that negativity and intensity of emotional reaction, and importance of the information, all significantly predicted relationship termination, the most influential factor being information importance. In 67.4 percent of the cases in which the relationship had ended, the discovery of deception was cited as the cause for the breakup.

Bolstering the findings of McCornack and Levine, Tim Cole analyzed the effects that deception had upon romantic relationship dynamics. He found that perception of a partner being dishonest had a substantial negative effect upon both commitment and satisfaction.

Of course, the preceding discussions raise the question, if people involved in romantic relationships can't detect deception, how is it discovered? In contrast to popular views that communicators detect lies on the spot by noting anomalous source behaviors, the bulk of actual deception detection occurs through incidental discovery. For example, Hee Sun Park, Timothy Levine, and colleagues examined self-reports from more than 200 individuals who recently had discovered lies. Their data suggest that, overwhelmingly, lies are discovered not through direct behavioral detection but instead through third-party information or the discovery of incriminating evidence. In only four instances in the entire data set did participants report having detected a lie through verbal and nonverbal behaviors at the moment it was delivered.

## Relationships: Sexual

Sex is a fundamental human need that serves many important purposes, both physical and psychological. When this need is strongly felt, some people will do just about anything in order to fulfill it, which may include telling lies or deceiving others in an attempt to get them into bed. People do not just lie in order to get sex, though—some people also deceive their partners during the sex

act. For instance, people may pretend to have an orgasm when they are ready for sex to end. In addition, people often lie about their sexual experiences after the fact. In some situations, under-reporting one's sexual history can yield benefits (e.g., protecting one's reputation), whereas in other cases, exaggerating or boasting about one's sexual experiences gives way to personal gain (popularity or fame). From beginning to end, lying and deception thus permeate many sexual relationships, and this has a number of important health and social consequences.

Decades of psychological research have demonstrated that people are often less than forthright when pursuing sexual partners. In order for someone to be sexually attractive, he or she needs to create a desirable impression. However, total and complete honesty will not always enhance sex appeal; sometimes, honesty can actually have the opposite effect. Deception is an easy way to enhance one's perceived desirability, and it is often successful. Consequently, deception is incredibly tempting in the seduction process, and is frequently employed, with studies indicating that one in four to one in five people admit having intentionally lied to another person at least once in order to have sex.

Some forms of sexual deception appear to be socially accepted, such as making minor alterations to one's physical appearance. This includes the use of makeup and hair dye, certain cosmetic procedures (such as breast implants), as well as specialty bras and underwear that enhance the appearance of one's bodily assets. However, there is a risk in modifying one's appearance too far (to the point where the deception becomes obvious), in which case there may be social penalties. Enhancing one's desirability by deceiving others about one's personal characteristics (such as lying about one's income, occupation, or achievements) or relationship history (hiding one's marital status and children), or by making false proclamations of love also happens with some frequency; however, these are less socially acceptable forms of deception.

Another way that people may attempt to enhance their perceived sexual desirability is by selectively revealing their sexual histories. For instance, when exchanging histories with a prospective romantic partner, people often report

that they are less experienced than they really are. Most commonly, this involves under-reporting one's previous number of sexual partners. Under-reporting sexual experience can reduce a partner's anxiety by creating fewer concerns about sexually transmitted infections (STIs); however, it can also enhance attractiveness in cultures where virginity is prized. Some women have taken this one step further by having their hymens surgically restored, with the goal of convincing their partner of their virginity. Many people view the presence of a hymen (a thin piece of tissue covering the vaginal opening) as proof of virginity; however, the presence or absence of a hymen is not necessarily a reliable predictor of virginity because activities other than sex (such as exercise) can cause the hymen to break.

In addition to under-reporting sexual experience, people frequently lie about having unusual sexual interests (fetishes), their previous condom use habits, and their STI history because they know that the truth might be a turnoff to certain partners. For example, persons with incurable STIs (such as HIV or genital herpes) often do not disclose their infection status to partners because they fear a negative reaction. In a review of studies concerning HIV disclosure among men who have sex with men, Kathleen Sullivan found that 12 to 33 percent of HIV positive participants reported failing to reveal their infection status to their primary sex partners. Such deception has important public health consequences because it makes it difficult for people to accurately assess their risks and take appropriate precautions.

### **Deception During Sex**

Perhaps the most common form of deception that takes place during sex is the false orgasm. Research by Charlene Muehlenhard and Sheena Shippee on college students found that 25 percent of men and 50 percent of women had previously faked an orgasm with at least one sexual partner. It is possible that males fake orgasm less because the male orgasm typically produces more physical evidence, which is more difficult to fake. Fake orgasms most commonly occur during sexual intercourse (as opposed to other sexual activities), and they typically involve some mix of bodily acting (clenching muscles and breathing faster) and vocal acting (moaning and screaming). Contrary

to popular belief, most people who have faked orgasms report having done so with an established romantic partner, as opposed to a casual partner they had just met.

People report a variety of reasons for faking orgasms, including the recognition that an actual orgasm was not going to happen, a desire for sex to be over, the avoidance of negative consequences (to prevent a partner from having hurt feelings), as well as to obtain positive consequences (pleasing one's partner). Research has found that men are more likely to have faked it because they wanted to be done with sex, whereas women are more likely to have faked it because they wanted to make their partner happy.

### **Sexual Deception in Other Contexts**

People do not just lie about their sex lives to their sexual partners—they also lie to the rest of the world. However, the nature of the lies told depends upon the nature of the audience, as well as prevailing cultural and societal views of sex. Politicians and celebrities frequently cover up their sexual histories (e.g., concealing a gay or bisexual identity, or denying an affair) in order to protect their moral credentials or reputation. In contrast, other persons may find that providing a more accurate account of or perhaps even exaggerating one's sexual history can yield personal gain. For instance, in some Western cultures, men are accorded popularity and social status for having an extensive sexual history, which may lead some men to embellish upon or boast about their past. Likewise, individuals who have affairs with prominent politicians or celebrities may choose to reveal that information (or even fabricate it in some cases) in the hope that it will become a springboard to fame and fortune.

Sexual dishonesty also occurs in scientific contexts, which hampers the ability to obtain an accurate understanding of human sexual behavior. Tendencies toward socially desirable responding have been well documented in the arena of sex research. In any scientific study, research subjects do not necessarily know who will see their responses or how their responses will be used. However, when given a survey about an especially personal and private matter such as sex, feelings of threat and worries about potential embarrassment can be very strong and promote an even

higher degree of dishonesty than usual. This is particularly true for women, who are under greater social pressure to maintain an appearance of sexual propriety. In a classic study by Michele Alexander and Terri Fisher, male and female college students were asked about their sexual attitudes and behaviors under one of three conditions. In the “bogus pipeline” condition, participants were hooked up to a polygraph and were falsely led to believe that the machine could detect whether they were telling the truth.

In the “exposure threat” condition, participants were not hooked up to a polygraph and instead were led to believe that one of their peers might be able to see their responses. In the “anonymous” condition, participants were assured that all of their responses would remain completely anonymous and were given complete privacy to complete the questionnaire. In general, women's responses tended to fluctuate more across conditions than men's. For example, whereas men reported having relatively similar numbers of sexual partners across conditions (3.7 to 4.2), the range for women was much larger (2.6 to 4.4). Moreover, women reported being the most sexually experienced in the bogus pipeline condition and the least experienced in the exposure threat condition (the anonymous condition fell in between). These findings indicate that women are more likely than men to consider the potential social consequences when reporting on their sexual behaviors and, therefore, may be more inclined to respond in socially acceptable ways.

In order to reduce tendencies toward socially desirable responding in sex research, scientists typically provide strict assurances of anonymity and confidentiality, which helps to some degree. Additionally, sexual scientists are increasingly turning to biological measures whenever possible (e.g., brain imaging and devices that assess genital arousal) instead of subjective self-reports because it is harder to fake physiological responses. The downside to biological measures is that they cannot answer all questions of interest (such as sexual history).

Lying and deception are common elements of human sexual relationships and are employed to achieve a number of distinct goals. For example, deceptive self-presentation may be used to obtain sex, fake orgasms may be used to end unsatisfying

sexual events, and selective self-reporting of one's sexual history may be used to maintain a certain social image. This tendency toward sexual dishonesty not only poses certain public health threats, but it also creates a number of challenges for scientists who study sexual relationships.

proponents believe that repression is a mental mechanism that helps individuals deny the reality of true traumatic experiences. On the other hand, critics of the concept of repression argue that efforts to "recover" repressed memories can lead to very rich, seemingly real, false memories for events that never happened. What these opposing views have in common is that both implicate repression in the self-deceptive functions of memory.

The concept of repression gained widespread attention from the writings of Sigmund Freud at the end of the 19th century. Freud argued that memories of traumatic, threatening, or otherwise unacceptable experiences can be repressed into the unconscious, where they are effectively walled off and inaccessible to the conscious mind, in effect, deceiving the repressor to falsely assume that things that did happen actually did not. Nevertheless, Freud argued, the repressed content remains accurately represented in the unconscious mind, and may leak from the unconscious into dreams and into waking life in the form of problematic clinical symptoms. Among the goals of therapy, as envisioned by Freud, was the reintroduction of the repressed content into conscious awareness, where it could be addressed and facilitate improvement of the symptoms.

Freud's theories have been highly influential in the therapeutic community, in which they formed the basis of three widespread assumptions: (1) that memories of traumatic experiences are particularly likely to be repressed; (2) that, while repressed, the memories do not fade but remain unchanged and undistorted for as long as decades; and (3) that they may be recovered unchanged through a variety of common therapeutic techniques. Each of these assumptions has been vigorously contested in a controversy that has come to be known among psychologists as the "memory wars."

## Repressed Memories

Among the most interesting ways individuals can deceive themselves is through memory. Though there are countless undisputed ways in which memory fails or becomes distorted, the concept of "repression" has been among the most controversial in modern psychology. On one hand,

### Repressed Memories of Sexual Abuse

This sharp division, largely between practicing therapists versus memory and clinical scientists, emerged in earnest in the late 1980s and early 1990s in response to increasingly frequent reports of memories of sexual abuse that had allegedly been repressed, sometimes for as long as decades, and later recovered by patients in therapy. In part,

these reports were fueled by the publication of several popular books arguing for the widespread prevalence of sexual abuse and of repression of memories of abuse, such as *The Courage to Heal: A Guide for Women Survivors of Child Sexual Abuse* (1988) and *Secret Survivors: Uncovering Incest and its Aftereffects in Women* (1990). These and similar books listed a large number of clinical symptoms alleged to reflect buried memories of sexual abuse and recommended various personal procedures to “recover” these memories and begin to heal the trauma of the abuse.

Along with increasing cultural awareness of the real prevalence of child sexual abuse, these publications encouraged many distressed people to attribute their symptoms to sexual abuse they

couldn't remember and to take action to recover their repressed memories of the abuse they assumed must have occurred. Similarly, many therapists were encouraged to attribute their patients' symptoms to unremembered abuse and, as a result, actively encouraged their patients to believe they had been abused and to undergo a number of therapeutic procedures with the goal of recovering the (presumed) repressed memories.

Concurrently, during the late 1980s and early 1990s some states relaxed their statutes of limitation, allowing criminal or civil actions to be filed based on testimony of those who claimed they had only recently recovered their memories of abuse or other crimes, sometimes many decades after the crime had allegedly occurred. The amended statutes began at the time the memories were allegedly recovered, rather than at the time of the alleged original events. This allowed alleged victims to file legal actions against parents, neighbors, priests, and others for abuse or other crimes based on alleged actions decades in the past, memories for which had been recovered in therapy.

In response to these events and to pleas for help from those claiming to have been falsely accused, some clinical and memory scientists began to contest such claims in earnest and to investigate the potential for many therapeutic techniques to plant false memories in those who undergo them. During the memory wars that followed, each side offered evidence favoring their positions that was largely discounted by the other.

### The Memory Wars

Proponents of repression have primarily focused on attempts to document real-life instances of repression of traumatic memories that were later recovered either spontaneously or during therapy or other memory recovery procedures. Two types of such studies have been reported. Retrospective memory studies have asked adults who report that they had been abused whether there had ever been a time when they forgot their abuse (referred to as the “do you remember whether you ever forgot” method). If they do report times when they did not or could not remember, their forgetting is considered to reflect repression.

Prospective memory studies identify apparently verified victims of abuse and follow up with them

*Sigmund Freud in 1926. At the end of the 19th century, Freud argued that memories of traumatic or threatening experiences can be repressed into the unconscious where they are effectively walled off from the conscious mind, deceiving the repressor into falsely assuming that certain events did not occur.*

later, inquiring about whether they had ever been abused. Those who do not report a memory of being abused are considered to have repressed the abuse. Though such studies purport to provide evidence of repression, they have been widely criticized for failing to establish one of the following necessary elements to establish repression and memory recovery: (1) that the original event did occur, (2) that the event was traumatic (otherwise repression should not occur), (3) that the person was unable to remember the event for a period of time, (4) that the person actually did not remember the abuse during the alleged interval of repression, (5) that the cause of the failure to remember was repression rather than normal failures of memory, and (6) that the “recovered” memories correspond to the verified instance(s) of abuse.

In contrast to the proponents of repression, memory and clinical scientists have widely argued that traumatic experiences are actually more likely to be remembered, that there is virtually no credible scientific support for the concept of repression, and that many suggestive influences within and outside therapy can cause the development of rich, false memories of events that never happened. Moreover, they have pointed out that highly implausible memories have been recovered in some therapies, memories such as past lives, in utero experiences, birth, memories before the age of 2, alien abduction, and satanic ritualistic abuse. Though many patients believe their memories are real and experience them as highly vivid and emotional, as is true for real traumatic memories, even such false memories as these can be generated through suggestive procedures.

Many laboratory studies have demonstrated that false autobiographical memories can indeed be created by common suggestive and therapeutic procedures, including suggestive questioning, hypnosis, guided imagery, dream interpretation, and others. Proponents of repression, on the other hand, have criticized such studies, suggesting while these influences may lead to false memories of relatively unimportant events, they are unlikely to do so for events as serious as sexual abuse and other traumatic events.

### **Repression and Deception**

Though the controversy over the reality of repression is unlikely to be fully resolved in the near

future, it is clear that there are many levels at which repression is implicated in deception of oneself and of others. Repression itself, if real, is a form of self-deception facilitating the denial of real, but unacceptable, experiences. Even if repression were to exist, efforts to recover the purported repressed memories can at least distort memories of real events, or worse, create rich, false memories for events that never happened. Either, in effect, can make the person an “honest liar” who believes in the reality of the memories, yet who is deceiving both him or herself and those who are told about the memories, with potentially devastating consequences for those implicated in criminal activities and for the families, relationships, careers, and lives destroyed by the allegations based on the memories.

Moreover, claims for the reality of repression and recovery of memories for crimes such as sexual abuse present opportunities for those who would deliberately deceive. Where there is potential for lucrative monetary awards, for revenge or punishment of a disliked foe, or for other practical gains, there can be temptation for accusers to knowingly lie, citing repression as a mechanism to explain why they had not previously reported the events in question. Some have argued that false claims of repression have been deliberately brought forth to help accusers negate the effects of a statute of limitations that would otherwise prevent a criminal or civil action after a specific period of time has passed.

Moreover, the self-deception and self-justification processes can affect the memories of those who begin with a knowing lie regarding repression. The knowing perpetration of a lie with devastating impact for the target can pose a significant threat to self-esteem. This can be averted if the person comes to believe the lie is actually the truth. Moreover, if the person needs to give the appearance of truth by entering therapy and otherwise behaving as if trying to recover a real memory, such activities can themselves create a false memory that seems real to the accuser. Thus, the liar might come to sincerely believe he or she was telling the truth all along.

Even the position one takes with respect to the reality of repression and recovery of traumatic memories is subject to processes of self-deception and self-justification. The monetary interests of

“recovered memory therapists,” for example, could motivate belief in the concept of repression and motivate denial that they could be promoting a false concept to distressed clients.

Altogether, given the entanglement of the issue of repression with the legal system, claims of repression have offered a fertile field for deception, whether deliberate deception for gain, or unintended self-deception and “honest lying.”

or dividing societies. Because of the importance of reputation in starting or continuing a personal relationship or business deal, or in gaining employment, individuals and groups engage in various efforts to control, shape, and protect their reputations. These efforts might include lying and deception or resorting to violence as means to protect or promote a reputation.

Psychologists such as Sigmund Freud, Carl Rogers, and Alfred Adler discussed various forms of lying and deception as psychological defense mechanisms that individuals might utilize in order to manufacture and protect their image in front of themselves and others. Such defense mechanisms, if overutilized, can contribute to various psychological symptoms. Some psychologists argue that keeping and creating one’s reputation in the form of a life narrative is a major human motive. Research on reputation has focused on the biological and evolutionary bases of reputation, types of reputation, the role of reputation in personal relationships and friendships, and the role of reputation in business. Recently, research has considered the consequences of the new Internet, technological, and communication advancements on reputation, especially among youth, and the mental and physical health consequences of reputation construction or damage.

Deception can be seen as part of nature. Camouflaging is a known natural mechanism in which an animal evolves to have physical characteristics that make it not salient in its background. In addition, some animals engage in deception in order to survive or project strength. For example, a tiger might hide before it jumps on its prey. Studies of both vertebrates and invertebrates have shown that social animals use reputation as a source of information about members of the group and their fighting abilities. Reputations can form by direct encounters or witnessing encounters with others. Once formed, a reputation can serve in survival and determine social hierarchy and strategies utilized in future conflicts. Moreover, the formation of a particular reputation can contribute to social order and a reduction in the frequency of conflicts. Misperceiving the abilities of another animal can result in dangerous consequences. From an evolutionary point of view, lying and deception in regard to reputation are not favored, because they interfere with the process of natural selection.

## Reputation

A person’s reputation—that is, the kind of person he or she is reputed to be—has been used through the centuries as a mechanism integrating individuals into larger social units, serving as a tool to punish those who do not adhere to a particular group’s social norms and values, and even uniting

### Types of Reputation

In regard to reputation among humans, researchers have classified reputation into three types: reputation as a property, as an honor, and as dignity. Reputation as a property is the major conceptualization found in the marketplace. According to this view, one labors continuously to build one's reputation, which is seen as a property essential in the marketplace, and one can re-establish the reputation if it becomes damaged.

When viewed as an honor, reputation is seen not as something earned through labor but as a form of recognition given to particular individuals because of the social role and status they occupy. From this perspective, individuals are expected to live up to the expectations associated with the role they occupy and the reputation associated with it. Damage to this type of reputation through lying and deception can damage the reputation of the social role itself.

Reputation as dignity is viewed as a consequence of being a member of a social group respected by both the self and others. Reputation here is not a property or an honor associated with a role but an integral part of identity. Damage to this type of reputation can have deep psychological consequences. Other research has focused on the role of reputation in the construction of self-identity, self-concept, and self-esteem; incongruity between one's self-image and one's reputation; and the possible psychological consequences of threats to this type of reputation.

### Reputation and the Internet

With the presence of the Internet and social media, self-identity among young people extends beyond real life and includes self-image and reputation on the Internet. In this case, the construction of reputation can be motivated by psychological and social objectives, and damage to one's reputation can have serious consequences for individuals faced with threats or actual damage to their reputation.

With the advancements in communication, the Internet, and social media, the consequences of lying and deception in regard to reputation have acquired new dimensions. Gossip, which once was limited to a few individuals or to small, identifiable groups of people, has become accessible to many, easy to find, permanent, and can be instigated by anonymous individuals. The loss

of control over one's reputation and privacy on the Internet is contributing to new psychological challenges. For example, cyberbullying has been found to be associated with anxiety, depression, and suicide among teens. Furthermore, some studies have found evidence for links between psychopathy and lying and deception in self-representation and reputation management.

### Reputation and Health Consequences

In addition, the desire to build a certain type of reputation has been found to be associated with health consequences. For example, an individual might engage in lying and deception in order to build or protect a reputation of health or strength. Such efforts can be seen among teens, among adults seeking to find a mate or to avoid social rejection, and among employees who are concerned about the consequences of a reputation for illness on their employment. Thus, the utilization of lying and deception to damage or promote a reputation can have serious consequences on individuals, physically, mentally, and socially, and on society in general.

## Résumés

Job seekers often have only one chance to make a first impression, and this impression usually comes in the form of a résumé. A résumé is used to showcase an individual's experience, knowledge, skills, and other pertinent background information. Most often, a résumé is used to obtain employment but it can be used for a variety of other reasons, such as gaining entrance to a graduate program, winning a scholarship or award, or securing a grant. Given the high stakes, much time is devoted to résumé construction. The process of creating a résumé can be considered a form of impression management, as it represents an attempt to control the image that others form of the candidate; however, when job seekers choose to use deceitful information, the degree of impression management used becomes an ethical concern.

Examples of once well-respected and high-ranking individuals who have been caught lying on their résumé are not difficult to find. Former Yahoo chief executive officer Scott Thompson

resigned his position in May 2012 after it was discovered that he lied about holding a bachelor's degree in both accounting and computer science from Stonehill College. His degree is actually only in accounting. Laura Callahan, former senior director at the U.S. Department of Homeland Security, resigned in 2004 after an investigation revealed that she had obtained her academic degrees by purchasing them from a diploma mill. Marilee Jones, who was the dean at the Massachusetts Institute of Technology, lied about her college degrees, and former Veritas Software chief financial officer Kenneth E. Lonchar was let go in 2002 after it was discovered that he lied about his M.B.A. degree from Stanford University and his accounting degree from Arizona State University. These stories are not just found among corporate-suite executives and other high-ranking officials. Many recruiters have example after example of fraudulent claims they have discovered on résumés.

### Consequences of Lying on Résumés

Getting caught may be the most obvious consequence of lying on a résumé. Once caught, an individual faces myriad legal and professional consequences. If discovered during the application process, the consequences are less extreme. Most likely, the offender will be rejected from the application pool. The consequences even at this stage, however, may be far-reaching as the applicant may never be considered for a position at that company in the future. If the hiring manager has a wide network of colleagues and business acquaintances and is ever asked about the applicant, a negative reputation begins to build and may prevent other job opportunities.

If the fraudulent claims are not noticed until the applicant has been hired, there are more potential consequences. The most obvious is immediate termination. Depending on how extensive the lie was and how pertinent it was to the current position, employers face a serious dilemma after realizing a position is currently filled by an employee lacking the necessary credentials. Perhaps more important, the employee is revealed as someone who is willing to deceive, and trust is now broken. Few employers would have reason to keep the employee.

In addition to individual consequences, there are organizational consequences. The costs associated with hiring an individual who has fabricated

parts of his or her résumé are high, especially at the executive level. What's more, if the exposed individual is high-ranking, the scandal can bring dishonor and embarrassment to the business or organization. Overall, résumé fabrication can detract from the accomplishment of an organization's goals.

### Reasons for Lying

Not surprisingly, there is a relationship between morale and willingness to lie. In an environment in which jobs are more difficult to come by, people are often afraid of staying unemployed. This fear can lead to desperation that is experienced over weeks or months of being without a job. Under these conditions, applicants are willing to engage in deceitful actions that are highly risky. For some applicants, the allure of a potential job is worth the risk. They rationalize their actions as something they need to do to get the job. Once rationalized, the behavior is no longer viewed as necessarily unethical.

Individuals are motivated to rationalize attitudes they hold and behavior in which they engage. Through this process of cognitive dissonance, people distance themselves from their wrongdoing, while justifying their actions. The brain is wired to continuously reduce the discomfort felt from transgression. Additionally, given that some sources estimate that half of all job seekers are lying on their résumés, many people may engage in falsification in reaction to a perceived threat that the competition will appear better in comparison. This threat may be quite real in actuality. Given the number of résumés found with fabrications, the honest individuals may be put at a disadvantage.

The most common areas of falsification on a résumé include employment history and education credentials. Job seekers have been found to lie about the length of employment, the reason for their departure, job titles, responsibilities and duties, accomplishments and rewards, and even the employers themselves. A quick Google search of this practice also reveals individuals who advocate making up employers, using non-United States-based employers that cannot be easily contacted for references, or using companies that have gone out of business in order to fill employment gaps on a résumé.

Job seekers will also include the universities and colleges that they attended and falsify the degrees they earned from those institutions. A surprising number of individuals have also been caught faking degrees and attendance days when they were not accepted or never attended the listed university. The advent of "diploma mills," which are online companies offering degrees and licenses with substandard or no academic study, and without recognition by any accredited educational institution, have made this practice even easier.

### Tips for Detecting Résumé Fraud

With even the simple technology that is available today, spotting fraudulent résumés is easier than ever before. A fairly simple way to verify credentials is to contact the references given by the applicant and perform checks on each of these references to ensure they are legitimate. When employers have narrowed the applicant pool, they should consider more thorough checks, especially for high-level positions. To verify education credentials, employers should ask the applicants to sign a release directing that an official copy of their transcripts be forwarded to the business or organizations to which the applicants are applying. Employers should also verify licenses with the appropriate issuing agencies.

U.S.-based employers can verify employment dates by requesting the applicant's Internal Revenue Service W-2 forms and by asking applicants to list the month and year of prior employment. It is also advisable to consider asking the applicant in great detail about past employment, including specific responsibilities. While this does take more time during the recruitment and selection phase, the employer could be saving a lot of time and money; investing in hiring and then training someone new is certainly more time-consuming and expensive.

### Conclusion

While résumé enhancement may allow applicants a foot in the door, the consequences are truly great. If it is discovered that an individual lied on a résumé, the integrity and character of that individual and, perhaps the entire organization, may be called into question. With the increased frequency that hiring managers are checking résumé

information, anyone considering lying on their résumé should truly consider whether the risk is worth the reward.

## Rose, Pete

Born Peter Edward Rose in Cincinnati, Ohio, Rose is one of four children of parents Harry and LaVerne Rose, who raised their family in the Western Hills working-class area of the city. At a young age Harry encouraged Pete's love for sports, and until his death Harry remained an important influence in his son's sports career.

Pete Rose's ambition for the sport of baseball is evident by his nickname, Charlie Hustle, given to him for his unique grit and energetic playing style. Rose enjoyed an illustrious 26-year career as both a player and manager. However, his career abruptly ended in 1989, after rumors of gambling led him to voluntarily accept a permanent place on Major League Baseball's (MLB) ineligible list. Rose was accused of breaking MLB's Rule 21, which states that any player, umpire, club official, or employee may not bet on any baseball game.

Rose made his debut as a player for the Cincinnati Reds on April 8, 1963, competing against the Pittsburgh Pirates, and that same year he won the National League Rookie of the Year Award. Rose played with the Reds until 1978, the Philadelphia Phillies from 1979 to 1983, and the Montreal Expos in 1984. That year, he rejoined the Reds as both a player and manager. Despite his numerous accolades, Rose became a controversial figure in the sport of baseball.

Three years after his final game as a player on August 17, 1986, Rose was questioned by outgoing MLB Commissioner Peter Ueberroth and his replacement, Bart Giamatti, in February 1989. Rose denied the reports that he bet on baseball, closing the investigation. Once Giamatti was named the MLB commissioner, he retained lawyer John Dowd to investigate charges against Rose. In 1987, Dowd documented Rose's gambling activities for the previous two years, compiling a day-to-day report of his bets. The investigation revealed that Rose bet on 52 Reds games, gambling \$10,000 per game. Dowd was not able to provide evidence that Rose bet against his own team.

Rose denied his involvement with gambling, refusing to appear at a hearing with Commissioner Giamatti. The case eventually moved to federal court, where Rose and MLB officials eventually negotiated a settlement. On August 24, 1989, Rose voluntarily agreed to a lifetime ban from baseball, signing a five-page document. In exchange for the ban, he asked MLB officials to refrain from making any formal findings of his gambling on the Reds. Rose adamantly denied gambling on baseball; however, Giamatti said he believed that Rose did gamble. Rose was replaced as Reds manager by Tony Helms. Giamatti died of a sudden heart attack at age 51 on September 1, 1990.

On April 20, 1990, Rose pled guilty to two charges of filing false income-tax returns, withholding information on the income he received from sports memorabilia. He was sentenced to a medium-security prison in Marion, Illinois, for five months and fined \$50,000. Rose was later released on January 7, 1991, after paying \$366,041 in back taxes and interest. Less than a month later, the Baseball Hall of Fame voted to exclude individuals who are placed on baseball's

Former Major League Baseball (MLB) player Pete Rose in Las Vegas, January 2008. In 1987, an MLB attorney compiled a day-to-day report on Rose's gambling activities from the previous two years, revealing that Rose gambled \$10,000 per game on 52 Reds games. Rose denied his involvement with gambling.

permanently ineligible list from being inducted into the Hall of Fame. Rose applied for reinstatement in 1997, but Commissioner Bud Selig never acted upon his application. After several years of denying his involvement with gambling, Rose publicly admitted to betting on baseball and other sports while playing and managing the Reds in his autobiography *My Prison Without Bars*, published on January 8, 2004.

Since then, there has been a show of strong support for Rose, who constantly reaffirms that he did not bet against his team. On September 12, 2010, Rose walked onto Cinergy Field, home of the Reds, to commemorate the 25th anniversary of his record-setting 4,192nd hit. Former Cincinnati Reds player Barry Larkin was inducted into the Hall of Fame on July 22, 2012. Among thousands of fans in attendance, Larkin thanked Rose, his former manager, during his induction speech.

At 4,256 hits, Rose is baseball's all-time leading hitter and the only living member on the MLB's ineligible list. With a career batting average of 0.303, numerous awards, and 18 MLB records under his belt—including most career outs, hits,

and games played—whether Rose deserves to be inducted into the Hall of Fame is still a controversial topic among baseball fans.

## Rumor

The spread of rumors is a pervasive aspect of American culture. The study of rumors spans many disciplines including anthropology, history, literature, communication, sociology, and social psychology. A rumor is an unverified explanation of an event, object, or issue of public concern that circulates from person to person, or an unverified relevant statement that arises during a situation of ambiguity, danger, or potential threat. In this context, rumors function to help people make sense of uncertainty, threat, or imminent danger.

Both of these definitions allude to the fact that (1) rumors are not verified, (2) a rumor has to be perceived as important enough to be passed

on, (3) individuals have to have confidence in the rumor, and (4) rumors are transmitted from person to person. As a rumor is transmitted, valuable information is lost. Person A receives the full rumor intact. Person B receives Person A's reproduction of the rumor, which is somewhat smaller than the original version. Each person receives a smaller quantity of the rumor. With each smaller quantity, the rumor is reduced in accuracy.

### Historical Perspective

The study of rumor is multidisciplinary, inclusive of rhetoric, sociology, and social psychology. In the field of rhetoric, Gordon W. Allport and Leo Postman conducted a study in 1947 differentiating a rumor from a legend. A legend is a "tall tale" that emphasizes the skill, wit, and exploits of an individual. It allows one to take pride in his or her culture. The motives behind transmission of a legend and a rumor are the same. They both emphasize the cognitive processes of forgetting, imagining, and rationalizing.

Folklorist Patricia Turner conducted research to determine how a traditional rumor is perpetuated among African Americans, publishing a book on this subject in 1993. Turner unearthed rumors such as drugs were deliberately planted in the black community by the Mafia and others trying to suppress the freedom of blacks, the Klu Klux Klan owned Church's Fried Chicken and several restaurants in the black community, and the Federal Bureau of Investigation (FBI) plotted to kill Martin Luther King, Jr. Turner found that rumor helped the African American community cope with white oppression.

Although rumor is multidisciplinary, empirical research and guiding theoretical perspectives largely come from sociology and social psychology. Sociologists study the collective nature of rumor and how rumor functions in society, while social psychologists study how rumor is transmitted. In fact, a preponderance of the empirical studies on rumor was conducted by behavioral psychologists. Rumors were studied in controlled conditions (for example, rumor clinics), and uncontrolled conditions (for example, rumors in the natural environment already in circulation). Altman and Postman wrote the seminal text on rumor—*The Psychology of Rumor*—and provided the impetus for future research.

### Rumor Transmission

Allport and Postman were among the first researchers to conduct a systematic study of rumor transmission and the psychological processes that affect it. They gathered their data in the 1940s from rumor clinics, including the Boston Rumor Clinic.

The two researchers reached eight conclusions based on their data: First, the flow of a rumor depends on its importance and level of ambiguity. Second, during the transmission of a rumor details are omitted, causing the rumor to be leveled. Third, in the same vein, materials that are not leveled tend to be made more important or sharpened. Fourth, distortions occur in serial messages; in addition, in some cases, the rumors become a substitute for the news.

Fifth, the transmission of a rumor can be represented quantitatively with the formula  $R = i \times a$ . In other words, rumor or "R," equals "i" (the importance of the rumor) times "a" (the ambiguity present in the rumor). This formula contains two key variables: ambiguity and importance. In analyzing the formula, a third factor is implied: a phenomenon that is defined as important or ambiguous varies from person to person. The variable "c" was added to this equation by Anthony Chorus to represent an individual's insight into social situations, taking into consideration such variables as social intellect, psychological insight, and individual differences.

The sixth conclusion in Allport and Postman's study held that when a rumor is cognitively unclear, there is an increase in transmission. Seventh, attitudes, needs, and motives affect whether a rumor is distorted during transmission or not. And eighth, when one considers attitudes, needs, and motives, rumor is a perceptual process similar to cognition, memory, and recall.

### Classifications of Rumor Research

Several researchers have attempted to categorize rumors. Mark Knapp, conducting research in 1944, classified rumor research into the following three categories:

- *Pipe dream rumors*. These rumors, later called "wish rumors" by other scholars in the field, are rumors that are positive in nature. For example, if a university

administrator was to make the decision that classes were cancelled because of the visit of the Dalai Lama, this would be a rumor of something most students would want to occur and would instill hope.

- *Fear rumors.* Later termed “dread rumors,” are rumors that are negative and may be induced because of ambiguity, threat, or danger. For example, if one were to say that underarm deodorant causes breast cancer, this would be a rumor deliberately planted to instill fear.
- *Wedge-driving rumors.* This is malicious gossip intended to cause harm to a phenomenon perceived as a threat.

Knapp’s classification scheme added to the body of knowledge in this area by categorizing the content of a rumor. It gave future researchers explanatory power and a means of organizing their data.

Years later, scholars reduced Knapp’s tripartite categories to two: wish rumors and dread rumors. In 1985, Fredrick Koenig identified three crucial aspects of a rumor: the target, the allegation, and the source. The target is the person, place, or thing being attacked with the rumor; the allegation is the rumor itself; while the source is the person originating the rumor.

Similarly, the research of R. L. Rosnow, conducted in 1974, classified three stages of rumor: parturition, diffusion, and control. Parturition is the birth of a rumor. Rumors originate for a variety of reasons. They could be coping mechanisms arising during times of fear, anxiety or uncertainty; they also could arise as a result of deliberate, malicious, intended gossip.

Diffusion refers to how a rumor is spread. Findings from a study conducted by S. C. Dodd in 1950 revealed that a rumor spreads faster in a small town than a bigger city. Further, results showed that a rumor spreads faster among friends than among strangers. The last category, control, refers to the cessation of a rumor. A rumor stops either when the facts are revealed or by natural death.

### Believability of a Rumor

Six major findings relate to the believability of a rumor: First, respondents believe a rumor more when the source is perceived to be credible.

Second, respondents tend to believe a rumor when it is consistent with beliefs they already hold. Third, when rumors coincide with pre-existing beliefs, a snowball effect occurs: new ideas are added to an already existing set of beliefs. If a rumor is false, it will continue to spread falsehood; if a rumor is true and checked for accuracy, the snowball effect stops.

Fourth, respondents will eliminate parts of the rumor to fit their existing set of beliefs. Fifth, respondents will conveniently forget information (selective retention) that does not coincide with their existing beliefs. Sixth, respondents will shape the rumor to coincide with their prejudices, stereotypes, and biases, thereby distorting the rumor and passing it on to others. These perceptual distortions occur with a lack of critical thinking.

# S

## Saint Augustine

Aurelius Augustinus (354–430 C.E.), or Saint Augustine, a saint and doctor of the Catholic Church, is the most important writer on lies in late antiquity, and one of the most important writers on lies of all time. He was the first thinker to systematically address the descriptive question of what is a lie, and the normative question of whether or not a lie is always impermissible. He was also the first thinker to address both of these questions in the light of Christian theology. He is one of the few thinkers (along with Saint Thomas Aquinas and Immanuel Kant) to hold that a lie is always impermissible.

Augustine discussed lying in many of his works, but he wrote two treatises devoted solely to the topic of lying: *Lying (Mendacio)*; 395), and *Against Lying (Contra Mendacium)*; 420).

It remains a matter of controversy as to what Augustine's final answer was to the first descriptive question of how a lie (*mendacium*) is to be defined, although much of his answer is clear. Augustine held that a lie requires "speech," that is, "words or . . . some other kind of signifying act," or more generally, the making of a statement. A statement is made in words or symbols—that is, conventional signs—that are spoken or written or otherwise expressed. For Augustine, it is not possible to lie by remaining silent. There can be no lie

of omission in that sense. It is also not possible to lie by using nonlinguistic or natural signs. It is not possible to lie by smiling, or groaning, for example. Although one can deceive by these means, one cannot lie by these means, as there is no statement.

Augustine held that a lie requires that the statement that is made be contrary to what one believes to be true: "He lies who has one thing in his mind and says something else." Augustine means by this that the liar (*mendax*) does not merely not believe his statement to be true but believes his statement to be false:

. . . the heart of the liar is said to be double, that is, twofold in its thinking: One part consisting in that knowledge he knows or thinks to be true yet does not so express; the other part consisting of that knowledge which he knows or thinks false yet expresses as true.

Someone who makes a statement that he neither believes to be true nor believes to be false is not lying. A lie therefore requires that the statement made be untruthful. If the person making the statement does not believe the statement to be false, then the person is not a liar, even if the statement that he makes happens to be false: "who utters falsehood does not lie if he believes or at least assumes that what he says is true." To make a statement that one believes is false is an

intentional act: “intention to tell a falsehood, i.e., what is, at least, believed to be false.” One cannot lie by mistake.

Augustine held that falsehood is not necessary for a lie and hence that a lie can be true or false: “that man is in conscience a liar who utters the truth thinking it to be false.” A person is judged to be lying or not lying on the basis of being untruthful: “he says what which he does not believe . . . even if what he does say be found to be true.”

Augustine appears to have considered all statement-making as a kind of testimony: “whoever pronounces any statement gives testimony to his own mind.” It follows that jokes, ironic statements, or lines delivered on a stage are not lies, as the person is not giving testimony to his own mind. Lies, it may be said, are assertions that are untruthful. What remains unclear, finally, is whether Augustine held that in addition to an untruthful assertion a lie requires an intention to deceive, either about the contents of the assertion, or about the beliefs or the intentions of the liar. Augustine provides an example of a person who makes an untruthful assertion to a mistrustful friend without the intention that the friend believe the following assertion:

Such would be the case of a man who, knowing that a certain road is besieged by bandits and fearing that a friend, for whose safety he is concerned, will take the road, tells that friend that there are no bandits here. He makes this assertion, realizing that his friend does not trust him, and will therefore believe that the bandits are there and will not go by that road.

About this case Augustine simply asks the question, “Is this a lie?” and does not answer it. It is certain, however, that he held that untruthful assertions that were intended to deceive were lies.

There is no uncertainty about Augustine’s answer to the second, normative question of whether or not a lie is always impermissible. Augustine condemns all lies: “Whoever thinks, moreover, that there is any kind of lie which is not a sin deceives himself.” Nevertheless, he believed that there were differences between lies: “It is my opinion, however, that every lie is a sin, though it makes a great difference with what intention and in what matter the lie is uttered.”

Some lies are worse than others. He divided lies into the following categories: (1) lies about religious doctrine; (2) lies that unjustly cause injury; (3) lies that benefit some and harm others; (4) lies told simply for the pleasure of telling lies; (5) lies told in order to please others “in smooth discourse”; (6) lies that harm no one and benefit some person; and subtypes of this sixth kind of lie, namely (7) lies that harm no one and that protect people from capital punishment; and (8) lies that harm no one and that protect people from physical defilement (principally, rape).

Although some of these lies are classified according to results (the second, third, sixth, seventh, and eighth types of lies), some according to reasons (fifth), and some according to content (first), all of them are lies, regardless of the content, the reason, or the result. The lie told for the pleasure of telling a lie he calls the “real lie.”

Although Augustine condemns all lies as impermissible, there are both theological and ethical arguments against lying in his writings. There are at least eight ethical arguments against lying. Lying is said to be impermissible because it is a perversion of the natural faculty of speech, because it is deceptive, because it involves breaking faith with an audience, and because it harms the liar. The four more indirect arguments are that lying undermines trust in society, that permitting one lie entails permitting all lies, that permitting lying entails permitting other evil acts, and that a permissible lie is a self-contradiction.

However, it is Augustine’s theological arguments against lying that are most important. The principal theological argument against lying is that speech is a gift from God, given to people to use as His gift for the purpose of expressing their thoughts. Lying is an appropriation of something that is not theirs, for a purpose contradictory to its intended purpose, namely, expressing what is not thought. This prideful appropriation of speech as something of their own, when it is actually God’s gift, ruptures the liars’ relationship with God, and disrupts a graced world of ordered being, goodness, and love. The exceptionless ban on lying is simply an instance of the exceptionless ban on sin.

## Santa Claus

Santa Claus is a fictional character recognized in the holidays of many European and North American cultures. While celebrating the secular aspects of Christmas, many parents willingly deceive their children into believing that Santa Claus will visit their home to bring gifts. Much controversy exists concerning this widespread, cultural deception. Upon hearing the truth, however, children typically do not feel betrayed; they instead take the truth as a rite of passage into adulthood.

The myth of Santa Claus coalesced from a number of cultural stories and traditions dating back to the 17th century, most from European/Christian regions. Saint Nicholas, a Greek religious figure in the early and mid-4th century C.E., was known for his acts of generosity and kindness to those in need, including clandestinely placing gifts and coins in individual's shoes. Removing even the Christian associations, the influence of this figure can also be traced back to pre-Christianized Germanic tribes' reverence of the pagan god Odin, a bearded old man who was thought to ride through the sky on his mystical horse.

The modern-day interpretation of Santa Claus owes much of its inspiration from Clement

Clarke Moore's 1822 poem "An Account of a Visit from St. Nicholas," more commonly known as "'Twas the Night Before Christmas." This poem described Santa Claus much as he is today: an old, overweight man who enters people's houses through chimneys on Christmas Eve in order to bring children gifts, flying from house to house on a sleigh pulled by reindeer. Since the introduction of this character and characters like him, parents all over the world have been happily deceiving their children.

The current practice of giving gifts around the Christmas holiday varies among Western countries, but the same pattern applies: children believe a mythical figure visits and leaves them with presents and candy. Whether these gifts are found in shoes, stockings, or under a tree, it is the parents' responsibility to deceive their children by secretly placing the items in these designated locations. "Evidence" of the visit by Santa Claus does not stop with the appearance of gifts: In places such as North America, many parents construct the visual remains of cookies and milk as "proof" that Santa Claus did indeed visit and enjoy a snack while inside the home.

Most parents who engage in the creation of a Santa Claus myth and the corresponding deceptive practices foster the idea with their children from a very young age. From the time a child is able to understand the concept of Santa Claus, parents reinforce the truth of his existence, even reassuring against doubts that occasionally arise, especially as the child increases in age.

There is some controversy about this practice of lying to children. One concern is that the role of parents as authority figures, sources of information, and conveyors of trust to children can be undermined. Other concerns focus on the potential to bias children's perceptions of the world when unrealistic and fantastical ideas are willingly promoted by adults.

There are several justifications of maintaining the Santa Claus myth and deceiving children. One argument is that belief in Santa Claus and the corresponding rituals tend to bring families closer together, while exploring creativity and cultural expression. In addition, this deception, while elaborate, is considered by many to be too small of a lie to cause any significant harm or distrust between children and their parents.

The discovery of the fabrication of Santa Claus is virtually inevitable and can take place in many ways at different stages of development. In many cases, the child finds out through a classmate, friend, or peer, either through direct or indirect contact. Television and film, while typically portraying Santa Claus as a real individual, may also contain instances of characters admitting to the fiction. In other situations, a child may stumble upon his or her parents while they are in the process of creating the fabrication (placing the presents in the designated location, eating the cookies). Rarely do parents simply tell the child they have been deceiving him or her.

After discovering the secret of their parents' deception, children generally do not exhibit a negative response. This is attributed to the child now embracing the feeling of being older and sharing a "grown-up" point of view and field of knowledge. Many children of this age desire to be treated as older than they actually are, and studies show that the discovery of the truth coincides more with feelings of happiness than with sadness. In fact, children's perceptions of the Santa Claus fantasy have been positively associated with cognitive growth and development. The thought processes required to foster this belief may encourage problem-solving in some children. Parents, in contrast, report feeling negative emotions upon their children's discovery of this deception. This response is due more to the discovery indicating the increasing maturity of the child rather than the detection of their deception.

The character of Santa Claus has a widespread origin, based on a number of stories and cultural archetypes. In spite of this, a common pattern of deception is carried out in each culture that celebrates his existence. Although some people disagree with deceiving children in this way, no significantly negative effects have been reported, and the practice remains a mainstay of the Christmas celebration.

## Sawyer, Tom

Lies and acts of deception play a significant role in the narrative of *The Adventures of Tom Sawyer* (1876), written by Mark Twain (the pen name of Samuel Langhorne Clemens). This classic tale of American youth proved popular enough to prompt Twain to pen several sequels: *The Adventures of Huckleberry Finn* (1884), *Tom Sawyer Abroad* (1894), and *Tom Sawyer, Detective* (1896). The work has remained an enduring part of the American literary canon, and it continues to occupy a prominent place in America popular culture, having inspired film and comic book adaptations and theatrical plays.

The prominence of lying in *Tom Sawyer* is not surprising, given Twain's literary preoccupation with truth and falsehood, which can found in works ranging from "The Celebrated Jumping Frog of Calaveras County" (1865), a comic short story depicting a gambler's use of cheating and deception to win a bet, to *Puddin'head Wilson* (1894), in which a black child's mother switches her light-skinned son with a white child in the hope of improving his lot in life by having him pass for white.

*Tom Sawyer's* title character routinely tells lies small and large, with outcomes ranging from comical to serious. The novel's very first chapter has Tom lying to his guardian, Aunt Polly, denying that he stole jam and played hooky. Like these, many of Tom's lies are exculpatory

attempts to avoid guilt and evade punishment. In one case, however, he does the reverse, chivalrously lying to protect his love interest, Becky Thatcher, from retribution for having damaged their teacher's prized anatomy book, claiming that he was the culprit and taking upon himself Becky's punishment.

The novel's second chapter features one of American literature's most iconic scenes, in which Tom displays sharp psychological insight in inducing his friends to pay him for the privilege of whitewashing a fence he was assigned to paint as a punishment. He deceives his friends into thinking the work is a rare privilege and not dull drudgery. Later, Tom leverages the loot gained from the whitewashing scam to trade for Sunday school tickets given to students for reciting Bible verses from memory; students who collect enough tickets are awarded their own Bible.

This leads to one of the novel's most comical scenes. Through shrewd trading Tom accumulates the number of tickets—representing 2,000 memorized verses—required to earn him his own Bible. During a special church event, which includes speeches and recitations by Sunday school students, Tom produces the tickets and claims his prize. When asked by a visiting dignitary to demonstrate his biblical knowledge by identifying the first two apostles appointed by Jesus, Tom delays and then, when pressed, reluctantly responds by naming David and Goliath.

Most of the lies Tom tells concern minor matters. There is one lie, however, that has life-and-death consequences. While visiting a cemetery at midnight as part of a superstitious cure for warts, Tom and his friend Huck Finn witness two local ruffians, Muff Potter and Injun Joe, robbing the grave of a recently deceased town resident under the direction of Dr. Robinson, who had paid the men in advance for the deed. Before carting the body away, Potter demands an extra \$5. This request leads to heated words and a fistfight that ends with Injun Joe using his partner's knife, which he had retrieved after it had fallen to the ground during the struggle, to kill Dr. Robinson. Injun Joe places the knife in the hand of Potter, who had been knocked unconscious. When Potter comes to, he concludes based upon the planted evidence that he has killed the doctor, and his devious partner affirms that Potter is the murderer.

Tom's witnessing this crime prompts the novel's major moral crisis. Fearing fatal retribution from Injun Joe, Tom and Huck swear to each other that they will not reveal what they had witnessed. However, Tom realizes that if they remain silent—essentially a lie of omission—a dangerous killer will go free, while an innocent man who had been kind to them stands to be condemned and executed for a crime he did not commit. This presents a moral dilemma that causes Tom nightmares. Eventually, he determines that the only right course is to reveal what he knows, regardless of any potential danger to himself. His court testimony exonerates Potter and clears Tom's conscience.

In *Tom Sawyer*, Twain clearly rejects the absolutist view of lying as always wrong. He does not depict all lies as bad, and in some cases suggests that lying might well be the right thing to do. Twain thus assumes a decidedly consequentialist perspective: there are good lies and bad, the moral worth of which is determined by whether they result in a positive or negative outcome.

There is, however, one curious case in which Tom's deception causes much suffering and exacts great cost, and yet even when the truth is revealed he enjoys a positive outcome. Seeking adventure, Tom and friends Huck Finn and Joe Harper run away from town to play at being pirates. When they stay away for several days, the town's men drag the river, presuming the boys have drowned, while the women and children stay home and grieve. Tom has it within his power to alleviate the sorrow of his family and friends, and put an end to the efforts to find him and his companions, by revealing the truth, but he elects not to do so. Instead, Tom delights in the cruel climax he has planned, when he and his friends dramatically enter their own funeral, to the amazement and relief of those present. Tom does not suffer any negative consequences for his sadistic deception; he is welcomed home rather than whipped by Aunt Polly and is treated as a kind of folk hero by his peers.

When it comes to lying, the warning with which Twain opens *Huckleberry Finn* seems equally applicable for that book's antecedent: when it comes to lying, readers should not seek any moral lesson from the narrative of *Tom Sawyer*.

## Scientific Content Analysis

Scientific content analysis (SCAN) is a verbal lie detection tool developed by the former Israeli police lieutenant and polygraph examiner Avi-noam Sapir. The tool is very popular and used worldwide. It is used by federal law enforcement (including the Federal Bureau of Investigation), military agencies (including the U.S. Army Military Intelligence Corps), secret services (including the Central Intelligence Agency), and other types of investigators, including social workers, lawyers, fire investigators, and the American Society for Industrial Security. Despite its widespread use, SCAN has not been the subject of much research. The scarce research findings available to date have not yet demonstrated that SCAN actually works.

### How SCAN Works

SCAN analyses are based on written statements. It is important that the statement reflects the examinee's own words. Investigators can transcribe oral statements, but preferably, examinees write their statements themselves because this reduces the risk of their statement being contaminated by the views of the investigator.

Examinees are requested to write down their activities during a certain period of time (for example, "What did you do from the time you woke up until you went to bed?"). They should write their statements in enough detail so that a reader without background information about

the examinee's activities could fully grasp the statement. Examinees are asked to write this statement when they arrive for their interview. The investigator is not present when the examinee writes the statement because there is a risk that the investigator's presence may influence the statement. Alternatively, examinees can write their statement at their preferred time and location and return it by mail or fax. The statement needs to be handwritten because one SCAN criterion examines the number of corrections made by the examinee. SCAN can be applied to statements from suspects and witnesses and can be used with adults and children.

The handwritten statement is analyzed by a SCAN expert on the basis of a list of predetermined but undefined criteria. The underlying assumption of SCAN is that true statements, derived from memory of an actual experienced event, differ in content and quality from statements that are based on invention or fantasy. The SCAN method provides no theoretical rationale for this assumption. A SCAN analysis is supposed to give insight into whether the examinee is truthful or deceptive, is trying to conceal something, or was involved in the crime. The SCAN expert uses the SCAN analysis to prepare him or herself for the interview. During the interview he or she will focus on aspects of the statement that raised concern or suspicion.

### SCAN Criteria

It is thought that some SCAN criteria are more likely to occur in truthful than in deceptive statements, whereas other criteria are more likely to occur in deceptive than in truthful statements. Examples of criteria include the following:

*Social introductions.* This refers to how the persons described in the statement are introduced. Truthful social introductions are thought to be unambiguous, for example, "My wife, Lisa."

*Spontaneous corrections.* This criterion refers to the presence of corrections in the statement, such as crossing out what has been written. Although explanations and additions are allowed, examinees are explicitly instructed not to cross anything out. A failure to follow this instruction could indicate deceit.

*Lack of conviction or memory.* Lack of conviction is present when the writer is vague about certain elements in the statement (“I believe,” “I think,” “kind of”) whereas lack of memory is present when the writer reports that he or she cannot remember something. SCAN investigators interpret lack of conviction or memory as suspicious.

*Structure of the statement.* This refers to the balance of the statement. It is thought that in a truthful statement the first 20 percent is used to describe activities leading up to the event, the next 50 percent to describe the actual event, and the final 30 percent to discuss what happened after the event.;

*Emotions.* This criterion refers to mentioning emotions in the statement, including at which point during the statement they are reported. It is thought that deceivers will mention emotions just before the climax of the story, whereas truth-tellers are more likely to mention emotions throughout the story but particularly after the climax of the story.

Other criteria SCAN experts use are “objective time” and “subjective time,” which refers to how different time periods are covered in a statement. Objective time refers to the actual duration of events described in the statement, whereas subjective time refers to the amount of words spent to describe these events. It is thought that in a truthful statement the objective and subjective time will correspond with each other in length, unlike in a deceptive statement.

Another criterion, “out of sequence,” examines whether the statement recounts the events in chronological order. A deviation of the chronological order of events is considered to indicate deception. “Extraneous information” examines whether there is information reported that does not seem relevant. If irrelevant information is provided, the SCAN expert should investigate why the examinee felt the need to include it. It is thought that examinees could include extraneous information to hide more important information.

The criterion “missing information” refers to phrases in the statement that indicate that some information has been left out. Examples are the use of words such as “sometime after,” “finally,”

“later on,” and “shortly thereafter.” Missing information is thought to be suspicious. In addition, statements are examined to determine if they are written in the first-person singular, past tense. It is thought that truthful statements are written in this manner because the writer describes an event that has taken place (“I saw the smoke coming out of the window”). Deviations from this norm should raise suspicion. Similarly, the use of pronouns, such as I, my, he, his, they, and their, signal commitment, responsibility, and possession. Omitting pronouns (“left the house” rather than “I left the house”) suggests the writer’s reluctance to commit him or herself to the described action. Leaving out pronouns that indicate possession (such as “my”) suggests that the writer denies ownership.

Finally, the criterion “change in language” refers to the change of terminology or vocabulary in the statement. A change in language indicates that something has altered in the mind of the writer. For example, if a suspect refers in his statement to all conversations he had as “conversations,” except one conversation that he describes as a “discussion,” it is likely that he perceived this conversation differently from the others.

### Research on SCAN

Research on SCAN is scarce. In a field study published in 1994, 30 written statements voluntarily given by suspects immediately prior to their polygraph tests were analyzed. The SCAN expert allocated 73 percent of the truthful and 95 percent of the deceptive statements correctly. These accuracy scores are high and often mentioned by SCAN users.

However, the study had an important limitation, as acknowledged by the author of the paper himself: it was unknown whether each suspect was actually telling the truth or lying. In technical terms, the “ground truth” was uncertain. It is a common problem in deception field studies that researchers do not know what truly happened in the cases that are included in their study. Ground truth can only be determined via facts (such as DNA evidence, fingerprints, credit card receipts, independent witnesses,) that indisputably link, or do not link, the alleged perpetrator to the crime. Such facts are often not present, which makes interpreting the results of field studies problematic.

A second SCAN field study was carried out in 2001 for the British Home Office. Three groups of SCAN users with different levels of experience, a fourth group of experienced detectives not trained in SCAN, and a fifth group of newly recruited officers also not trained in SCAN analyzed 27 real-life statements. As was the case in the first field study, ground truth was not established. The three groups of SCAN users performed well and correctly classified at least 80 percent of the truths and 75 percent of the lies. However, so did the experienced detectives untrained in SCAN, and so the study therefore showed no benefit of using the technique. This field study also revealed that different SCAN experts used different SCAN criteria to justify their decision of whether or not a statement was deceptive. In other words, there was a lack of consistency in the application of SCAN among SCAN users.

In one further published SCAN study, a laboratory experiment, truth-tellers truthfully wrote down their activities during the previous half hour, whereas liars were asked to fabricate a story. The statements were analyzed with SCAN and, by way of comparison, with reality monitoring (RM), another verbal veracity tool. SCAN did not distinguish truth-tellers from liars above the level of chance, but RM did. With RM analyses, 71 percent of truth-tellers and liars were correctly classified.

There is some overlap between SCAN criteria and the criteria in yet another verbal veracity tool, Criteria-Based Content Analysis (CBCA). For example, the criteria lack of memory, out of sequence information, and extraneous information, appear on both lists. Intriguingly though, the predictions about how these criteria discriminate between truth-tellers and liars differ. In CBCA, the occurrence of these cues is perceived as indicators of truth, whereas in SCAN the same criteria are seen as indicators of deceit. Research regarding these individual criteria (all laboratory studies) gives support only to the CBCA assumptions.

### Conclusion

Two field studies revealed high accuracy rates in using the tool, but the same high performance was achieved by non-SCAN users. The SCAN laboratory experiment and the CBCA laboratory experiments showed no support for SCAN. In

sum, SCAN is popular among practitioners and widely used. There is not much research into it, but research carried out has yet to demonstrate that SCAN actually works.

## Secrecy

Secrecy can be conceptualized as the intentional act of keeping information contained, such that it may be known to select individuals or groups but not to other individuals or groups. Some suggest that secrecy is passive deception while lying is active deception, though it can be argued that mentally juggling information in order to maintain secrecy is just as active a process. Secrecy may also be a reason for lying or deception. For example, a battered spouse who wishes to protect

the perpetrator may fabricate excuses for injuries or use cosmetics to cover bruises. Secrecy is common in that most individuals are able to identify at least one piece of information that they do not reveal freely. Complete secrecy (that is, a secret that is concealed from everyone), however, is rare.

Generally, the type of secrets people keep fall into categories varying from taboo (that is, strongly stigmatized by society) to conventional (that is, information that people normally keep private). Topics range from shameful to traumatic, past experiences to current health concerns, and often relate to sex or past relationships. Research on family secrets has identified several reasons for secrecy that have been applied to work on general secret keeping. In particular, a strong reason for secrecy is to avoid the negative evaluation of others. People may also withhold information because they feel it is private (that is, not relevant to others), to protect themselves from people who may use the secret against them, or because they find it difficult to communicate about the problem. They may also keep secrets as a relationship-protective measure; for example, they may wish to bond with others who share the secret or to maintain good relations, rather than create trouble.

### Consequences of Keeping Secrets

The consequences of secrecy appear ambiguous in the existing literature. In studies of both clinical and normal samples, the act of keeping secrets has been linked to negative well-being. These effects may manifest themselves psychologically (for example, stress, anxiety, depression) or physically (e.g., bodily symptoms, illness). Researchers have proposed several models as possible explanations for this connection. For instance, inhibiting thoughts or being preoccupied by thoughts about the secret involve continuous mental effort and prevent a secretkeeper from escaping the secret. Not sharing a secret may also rob a person of the opportunity to receive the support needed to cope with the problem.

Some studies found that people who are keeping serious secrets are also more likely to overestimate physical burdens, such as expecting physical tasks to require more effort or offering others less assistance with physical work.

Additional research has found improvements in the health of secret-keepers after a secret is disclosed. However, other research suggests that poor outcomes result only when a secret is serious and that secrecy may not always be detrimental. It may protect others from information they do not need to know, and it may be a way for individuals to maintain independence and their own sense of identity.

Secrecy may also damage relationships. When secret-keepers are not forthcoming with information, the people around them may feel alienated or rejected. They may also trust the secret-keeper less if they suspect or know that the secret-keeping is hiding something. Based on longitudinal research studies, secrecy may lead to less closeness, satisfaction, and commitment in personal relationships. However, avoiding topics that are points of contention or sources of negative emotion can also be a way of maintaining peace in a relationship.

### Conditions of Revealing Secrets

Research suggests several conditions under which people decide to reveal a secret; in particular, they are more likely to share their secret when they feel emotionally close to a person or when they are concerned that the secret will eventually be revealed. Having a confidant who is nonjudgmental and supportive also increases the likelihood of secret revelation. Positive secrets are also likely to be shared, as well as secrets involving the escalation of a romantic relationship (for example, wishing to turn a dating relationship into something more serious).

However, people are least likely to reveal a secret voluntarily when they expect disapproval or other negative reactions, or when they wish to preserve their relationship with the potential confidant and other individuals relevant to the secret. Privacy (that is, the secret is not relevant to the confidant) and communication problems (that is, the secret-keeper is unsure of how to broach the topic) are also cited as conditions that promote an individual's continued secrecy. Secret-keepers also tend to predict that confidants will react more negatively than they actually do when a secret is revealed. Curiously, once the secret is revealed, secret-keepers may believe they accurately predicted the confidant's reaction.

### Benefits and Pitfalls of Disclosing Secrets

There are some benefits to disclosing a secret. In close relationships, such an act is a show of trust and may help foster bonds between family, friends, and lovers. If the secret involves a problem the secret-keeper has been enduring, bringing the information out into the open can be a step toward receiving help or achieving closure. Based on the confidants' reactions, secret-keepers may realize that the secret is not as terrible or shameful as they might have assumed.

Nevertheless, the pitfalls of revealing secrets are also numerous. The confidants themselves may find it impossible to keep the secret, repeating it to others more than half the time. Additionally, although secret-keepers may find it cathartic to share a troubling secret, the confidants now face the prospect of shouldering a burden they may not have wanted. The confidants may also wish to provide support but not know the best way to do so, and as a result, secret-keepers seeking support or acceptance may not find confession to be the remedy they desired. For these reasons, unburdening one's secrets to others is not always recommended.

### Conclusion

To conclude, secrecy is a fundamental feature of the way humans relate. Researchers have identified relatively consistent reasons for protecting information; the most prominent reason involves a desire to protect oneself or someone else from negative evaluation. Often, the secret involves a taboo. Research on the consequences of keeping a secret is mixed, with some suggesting poor physical and mental health outcomes and others proposing that secrecy can be beneficial. Certain conditions are likely to yield secret confessions, namely, having an accepting confidant with whom one is emotionally close. Revealing a secret may have both positive and negative consequences.

## Self-Deception

Lying typically involves (at least) two people: a subject S who lies and a target T who is lied to. S intends, by asserting that some belief ( $\beta$ ) is true, to make T believe that  $\beta$  is true, even though S knows  $\beta$  to be false. Thus, one person, who knows something, sets out to deceive another person, who does not.

Reasoning by analogy, self-deception would seem to involve the same person setting out to deceive themselves (and succeeding). But this seems impossible on the face of it. How can a single person play the roles of S and T, both sending and receiving a misleading message, both knowing that  $\beta$  is false and believing it is true? Much philosophical analysis has attempted to square this conceptual circle. Whether or not it succeeds is moot.

Despite the paradoxical nature of self-deception, everyday examples are easily envisaged. A persistent hard-drug user boasts he can kick his habit whenever he wants. A student who keeps skipping class insists she wishes to pursue an academic career. A husband who habitually cheats on his wife swears that he loves only her. Here, actors stubbornly deny what observers can readily perceive: their problematic deeds imply character flaws.

Such everyday examples highlight how self-deception is not merely accidental—a type of

cognitive error. It is also motivated—a type of wishful thinking. In particular, the desire to maintain a positive self-view, to self-enhance, lies at the heart of much self-deception. To admit to a character flaw—to being, say, an addict, idler, or cad—entails a psychic cost in the form of lower self-esteem or social shame. To avoid incurring that cost, the admission is avoided. Thus, every act of self-deception involves denial, a classic defense mechanism.

Self-deceptive denials range from moderate to extreme. Suppose one pays a sizeable sum to see a movie, but the movie disappoints. The conclusion that one wasted money, or was foolish enough to do so, is unwelcome. It can, however, be avoided by concluding that the movie was better than it was. Such rationalizations are convenient ways of resolving otherwise dispiriting cognitive dissonances. More unqualified forms of denial surface in clinical cases of narcissism. Here, the motive to self-enhance predominates so strongly that arrogant self-justification becomes routine and invincible.

### What Mechanism Underlies Self-Deception?

Can the paradox of self-deception be resolved? If people do not literally lie to themselves by dividing themselves into two distinct and antagonistic centers of consciousness, how does the process work psychologically?

One promising model draws an analogy with junk mail. Sifting through one's mailbox, one attempts to separate mail one wants to keep from mail one wants to discard. To do so effectively, it is not always necessary to open every envelope. Superficial inspection of the envelope itself—is it familiar and formal, or glossy and generic?—often suffices to reliably identify each item.

A similar dynamic may characterize self-deception. That is, self-deceivers may indeed suspect that their problematic deeds carry unflattering implications. However, they do not need to unpack that suspicion fully to be disturbed by it. Even “unopened,” it contains enough cognitive cues to signal that it is unwelcome. Accordingly, self-deceivers may opt not to dwell on its “contents.” The suspicion accordingly passes out of their minds, to be replaced by more reassuring reflections.

Formally put, the mechanism underlying self-deception may be this: more elaborate processing

of information is short-circuited if less elaborate processing hints that it poses a potential threat, especially to one's positive view of self. Hence, there is no need to postulate two selves inhabiting one mind: one the deceiver, and the other the deceived. There may be no need even to postulate the coexistence of two conflicting beliefs. An uncongenial belief may be nipped in the bud before it gets the chance to properly compete with a congenial one.

This junk-mail model is consistent with several findings from experimental research. For example, people selectively forget critical (but not flattering) feedback that pertains to personality characteristics that they regard as of primary (but not of secondary) importance to their identity. This suggests that, on receiving the feedback that they tend to forget, people do not dwell on it as much, or do not process it as elaborately, as the less disturbing feedback that they tend to recall.

### Can Self-Deception Be Experimentally Demonstrated?

Examples of self-deception are easily enumerated. However, they still involve some degree of subjective interpretation. Accordingly, they may be mistaken, like the far-fetched diagnoses of some Freudian psychoanalysis. Three studies offer

*Despite the paradoxical nature of self-deception, everyday examples abound; for example, a persistent hard-drug user boasts she can kick her habit whenever she wants.*

classic examples of the direct experimental demonstration of self-deception.

In one study, participants initially had their self-esteem lowered or raised by informing them that they had performed either poorly or well on a bogus examination. Next, they listened to audio recordings of varying durations. Some featured their own voice, some other people's voices. Participants had to distinguish the one from the other. In addition, participants had their levels of physiological arousal concurrently assessed.

Hearing one's own voice normally increases arousal because one implicitly recognizes it. This was also the case here: increased arousal reliably indicated the playing of one's own voice. However, in some cases participants mistakenly denied hearing their own voice when it was played, and in others mistakenly affirmed hearing their own voice when it was not. Crucially, false denials were more common among participants who had had their self-esteem lowered, whereas false affirmations were more common among those who had had their self-esteem raised. This suggests that feelings of shame or pride made participants either reluctant or keen to identify themselves at a conscious level. Nonetheless, they still always identified themselves at an unconscious level. Here, participants seem to deny that they were experiencing particular perceptions.

In another study, participants were led to believe that two types of heart existed: the Type I sort, predicting longevity, and the Type II sort, predicting the opposite. They were also led to believe that the length of time they could keep their forearm submerged in a bath of ice water—either for a longer period or a shorter one—reliably indicated which type of heart they had. Upon taking the relevant test, participants acted so as to modify the amount of time they kept their forearm submerged in the direction that implied a greater likelihood of possessing the desirable Type I heart.

However, before taking the test, participants would either have possessed a Type I or a Type II heart. This fact would not have changed in the course of the experiment. Hence, it would have been pointless for participants to strive to submerge their arm for a longer or shorter period. That is, their performance on the test could only have been diagnostic of the type of heart they had,

but it could not have had any causal impact on it. Yet if participants “accidentally” found themselves keeping the hand submerged for a longer or shorter time, then they would have been free to regard the reassuring test result as real. This is exactly what happened in this experiment, in which participants seemed to deny that they were acting on particular intentions.

A final study featured male participants who all claimed to be entirely heterosexual. They were divided into two groups: those who also reported being homophobic, and those who did not. Both groups watched three types of erotic movie clips: heterosexual, lesbian, and gay. As they watched, their penile circumference was continuously monitored with a plethysmograph.

Both homophobic and nonhomophobic participants showed substantial and equivalent arousal to heterosexual and lesbian clips. However, the homophobic participants also showed mild arousal to the gay clips, whereas the nonphobic participants showed next to none. This pattern of findings is consistent with homophobia at least partly deriving from a latent bisexuality deemed morally unacceptable. Here, participants seemed to deny that they entertained particular desires.

### Why Does Self-Deception Occur?

Self-deception entails irrationality. People cling to positive illusions about themselves in the face of contradictory evidence and despite the practical risks of misjudging themselves. Why would they do so? Several hypotheses have been advanced. Some contend that self-deception is a structural by-product of how the mind generally works. Others contend that self-deception is a functional adaptation facilitating survival and reproduction. Both classes of hypothesis are complementary rather than contradictory.

Structurally, self-deception may arise naturally out of the modularity of the human mind. If somewhat autonomous mental units each perform their own specialized tasks, then one would not expect them always to operate in concert. This view can be readily harmonized with the junk-mail model above.

Functionally, self-deception may assist the deception of others. Suppose—because of sex differences in reproductive biology—men generally seek to mate widely, whereas women generally

seek to mate wisely. If so, then men may evolve to deceive women about their fidelity, and women evolve to deceive men about their availability. As a counterstrategy, both sexes may then evolve to see through one another's deception.

What next? One counter-counterstrategy would be for both sexes to deceive themselves into believing—at least at first—they are offering what the other sex really wants. By doing so, there would be no more deception to detect. Analogously, it may also be advantageous for people to deceive themselves about their intentions in other relationships, whether cooperative or competitive.

## Self-Esteem

Self-esteem refers to how one would evaluate his or her self-worth, which is derived from one's own experiences, beliefs, and self-perception. Sigmund Freud breaks self-esteem into three components: one's aspirations for oneself, one's aspirations that are corroborated by actual experience, and one's loving and being loved by others. Being loved by others can be falsified when people alter their true identities in order to be more desired and approved by society. One's own self-esteem can be falsified because those with high self-esteem tend to overestimate their own abilities and traits, and those with low self-esteem tend to more accurately predict their own abilities. Self-esteem in this case functions as a form of self-lying in order to increase feelings of accomplishment and satisfaction.

Until recently, it was believed that self-esteem was a consequence of life outcomes, including job satisfaction, salary information, relationship outcomes, personal health, and depression. More recent research indicates that life outcomes do not have direct effects on self-esteem. Conversely, self-esteem does seem to predict life outcomes. Even though the effects are often small, self-esteem affects relationships, job satisfaction, and health. However, self-esteem has not been found to be related to occupational status.

Taken across outcomes, self-esteem plays a large role in overall life consequences. Those with higher self-esteem tend to be more healthy and satisfied with multiple aspects of their lives. Similarly, those with lower self-esteem tend to be less healthy and less satisfied overall.

### Defensive Self-Esteem

When individuals have high self-esteem combined with a high need for approval, it has been

suggested that they are high in defensive self-esteem. Defensive self-esteem occurs when an individual falsifies his or her behaviors to avoid criticism, hostility, and unfavorable opinions about themselves. In effect, they report high levels of self-esteem targeted on a version of their self that is manufactured to obtain the approval of others. Two underlying factors of socially desirable responding have been found to affect defensive self-esteem: impression management and self-deception.

Impression management occurs when individuals are fully aware that he or she is changing their own behaviors in order to be approved. Most people utilize impression management, such as in the job interview process and on social networking sites, in order to appear more socially acceptable. Having control over what others see and hear are only two aspects of making an impression. Social media makes it easier to mask one's personality, focusing on one aspect instead of personality in its entirety. For example, one could focus solely on philanthropy, making the individual appear to be more generous, but no other aspect of his or her personality would be noted. Impression management also includes having more control over self-presentational behavior.

Self-deception is said to occur when an individual simultaneously and unknowingly holds two opposing beliefs regarding his or her behaviors and feelings of self-worth. Self-deception has been suggested as a response to self-confrontation, and individuals may or may not elicit contradictory beliefs about themselves during self-report measures. As such, self-deception can be defined as an unconscious bias that protects an individual's self-esteem against psychological threats of being inadequate, incapable, or undesirable. When confronted with information regarding themselves that would threaten their self-esteem, they convince themselves this information is not a true reflection of themselves.

A recent study demonstrated that when self-esteem is low, there are stronger feelings of pleasure arising out of the misfortunes of others. The misfortune of others provides a downward comparison that can boost a person's own feelings of adequacy. Those with higher self-esteem do not feel as strongly about self-protection because they are desired and accepted by society.

Similar to projecting deceptive self-esteem and misrepresenting oneself in order to be more socially acceptable, self-esteem is related to individuals' perceptions of their own capabilities. When asked to rate one's self-efficacy, those that rate higher on self-esteem scales tend to have higher self-efficacy ratings as well. This belief is somewhat skewed, however, as individuals tend to believe they are more capable than they actually are when tested. Conversely, those with lower self-esteem ratings tend to rate themselves more accurately on self-efficacy scales.

This is also seen on social media sites because such sites allow people to filter what they want to be publicly viewed, stated, or projected. Social media allows more control over self-presentational behavior compared to face-to-face contact. Those with higher self-esteem tend to have more friends or followers on social media sites, and they share disproportionately more positive activities and pictures depicting themselves in positive activities compared to people with lower self-esteem. Over-sharing or inappropriate sharing, such as pictures of alcoholic excesses, are more likely to be posted by those with lower self-esteem.

### Measuring Self-Esteem

Self-esteem can be measured in various ways. Self-esteem was initially measured through the analysis of verbal interviews. These interviews were more likely to capture an individual's self-esteem as projected through impression management and self-deception. Interviews may also fail to capture self-views that individuals may not be consciously aware of. Even if they are aware of their self-esteem, individuals may give inaccurate responses as a method of defensive self-esteem.

More recent research on self-esteem uses various self-report rating scales. The Rosenberg Self-Esteem Scale is one of the first scales created to measure self-esteem and is still widely used today. This 10-item scale provides a range of self-esteem: the higher the rating, the higher the self-esteem an individual possesses. Though explicit rating scales such as the Rosenberg Self-Esteem Scale have high internal consistency, they can easily be falsified, as with interviews, because they are self-report measures. Self-report measures can be unreliable because some individuals may not be aware of their own self-esteem and may give

responses that they believe are accurate but actually are an inaccurate measure of the individuals' true feeling toward themselves.

Because of the inaccuracies of the Rosenberg Self-Esteem Scale and other self-report measures, researchers have begun to utilize the Implicit Association Test (IAT) to measure implicit or unconscious self-esteem. The IAT requires participants to associate certain words to either themselves or to others. Through the IAT those individuals with genuinely high self-esteem will relate more positively associated words to themselves. Those with lower self-esteem relate less positive words to themselves and more positive words toward others.

The Name-Letter Test, or NLT, has also been developed to measure self-esteem. Individuals are asked to rate their liking for all the letters of the alphabet. When comparing letters, the initials of the names of those who report high self-esteem are rated higher than the ratings of other letters. Items that represent the self are rated higher than the items that are not representative of the self. The NLT or the IAT provide additional tools to measure self-esteem. Such methods are needed, as self-esteem by its very nature is often deceptive.

Self-esteem in relation to lying and deception is in individuals' ability to lie to themselves or to others regarding their sense of self. Such lies of the self can include pretending to be something they are not, thus deceiving others about their true personalities, or deceiving themselves through exaggerated appraisals of their own traits and abilities through high self-esteem. Those with high self-esteem rate facets of themselves as unrealistically high compared to those with low self-esteem. Similarly, those with high self-esteem rate their self-efficacy less accurately than those with lower self-esteem. Such scales also display that when someone has low self-esteem and encounters something that may be detrimental to his or her self-esteem, he or she is more likely to engage in self-deception to protect the good feelings that go along with high self-esteem.

## Self-Justification

The most insidious form of deception is self-deception. When an individual deceives others (as in a political speech), that deception may temporarily affect the attitudes and behavior of the audience. But if the deceiver then needs to justify what he has done and succeeds in deceiving himself, the effects on his attitudes and behavior are often profound and long-lasting.

Scientific research on self-justification and self-deception began in earnest in 1950, when Leon Festinger invented the theory of cognitive dissonance. Basically, cognitive dissonance occurs when an individual holds two cognitions (ideas, beliefs, attitudes) contradicting each other. Dissonance produces mental discomfort, from minor pangs to deep anguish. People do not rest easily until they reduce this discomfort, usually by modifying one cognition to make it more consistent with the other.

As a student working in Festinger's lab, Elliot Aronson made an important discovery: cognitive dissonance causes most pain, and therefore the most permanent changes, when one of the cognitions is about the way individuals see themselves and the other is about an action they perform or a statement they make that runs counter to that self-concept. Elaborating on that insight, Aronson suggested that because most people consider themselves to be relatively smart, moral, and competent, when they do something that makes them feel stupid, immoral, or incompetent, they experience the greatest pain of dissonance. Because it is virtually unthinkable for people to change their beliefs in the kind of persons they are ("I guess I am a stupid, immoral slob after all!"), they strive, instead, to invent a story that justifies the action that threatened their self-concept.

There are a great many ways for individuals to justify their actions, but they usually involve constructing a story that enhances the value of the action they have taken, that diminishes the importance of the unethical behavior in which they have engaged, or that dehumanizes the person they have harmed. Fifty years of research has supported these ideas.

### Research in Self-Justification

In a classic experiment by Festinger and Merrill Carlsmith, participants were asked to lie by falsely telling an incoming participant that the excruciatingly boring task they had just performed was actually fun and interesting. In subsequent experiments, participants were asked to lie to others about what they really thought: to publicly argue in favor of a position they were actually strongly against. Some participants were paid well for their misrepresentations, and others poorly. Participants who were paid well, or were offered other strong incentives or justifications for their behavior, seemed to feel no dissonance and no need to tell themselves any further story about why it was okay to lie. But those who were not offered adequate justifications came up with their own, typically by deciding that they weren't really lying. They really believed what they said, and they were doing good by convincing others.

While early studies focused on lying or other harmful behaviors toward others, research soon

showed that individuals feel compelled to justify foolish behaviors as well: lying to themselves is an effort to feel good about their choices. But people often suffer from these self-justifications, finding it difficult to abandon foolish choices, to admit their mistakes and move on. With blinders shielding them from awareness of their mistakes, they persist in walking the same flawed paths. The worse the mistakes, the harder they work to justify them to themselves and others.

A laboratory experiment by Elliot Aronson and Judson Mills further illustrates how these processes work. College students volunteered to participate in a series of group discussions on the psychology of sex. Some students were randomly assigned to a control condition, which allowed them into the group with little or no effort. Others had to go through a great deal of effort to be admitted to the group. Each volunteer then listened to what they believed to be a live discussion by the group they had just joined (actually a standardized recording of a terribly boring and tedious discussion).

The students in the control group saw it for what it was, a boring and worthless group, and they had no wish to come back for another meeting. But those in the high-effort condition rated the group as worthwhile and enjoyable; they could hardly wait for the next meeting. Why? The cognition, "I went through hell and high water to get into a boring group" was dissonant with their self-concept of being smart. They needed to tell themselves a story that would allow them to see the group in the best possible light.

The process of self-justification works below conscious awareness. For example, after his experiment, Aronson explained the theory and hypotheses to the students. The typical response of those in the high-effort condition was, "Yes, I understand the theory; it sounds reasonable. But it's not true for me. I really liked that discussion. I really do consider it an interesting group and I am unhappy that I can't join it."

In much the same way, other researchers have found a host of additional results showing the power of self-justification. Summarizing this search, Carol Tavris and Elliot Aronson concluded that self-justification is most destructive when it allows individuals to engage in immoral behaviors that cheat or harm others. This is

when individuals can get truly creative, often by blaming their own dishonest or hurtful behavior on the victims themselves, deciding they were unworthy and deserved the abuse that was heaped on them.

Although all people spin masterful tales of self-justification, some people are more clever than others. Dan Ariely has described many instances of real-life cheating among professionals as well as among participants in laboratory studies. He found that cheating was quite pervasive, but one group stood out as the most likely cheaters. Just as self-justification theory would predict, it was the most creative people—those who could tell the best stories to justify their cheating—who cheated the most. A lifetime of creative self-justification seems to allow people to find a way to feel good about whatever they want to do whether it is deceiving others without remorse, or engaging in unhealthy behavior (such as smoking, overeating, or underexercising).

Fortunately, creative self-justification can also push individuals toward useful behaviors. For example, considerable effort, sacrifice, or commitment can be a necessary requirement making the right choice. As dissonance researchers have shown, the need to justify these “costs” of doing the right thing can drive people toward more responsible actions, for example, to behave more ethically, practice safer sex, conserve water, or exercise more regularly.

## Conclusion

Self-justification processes are powerful and ubiquitous. They lead sensible people to deceive themselves in countless ways in everyday life. Most important, these changes are far from ephemeral. For good or for evil, they can exert lasting and powerful effects on a person's beliefs and behavior.

# Sender Demeanor

Sender demeanor refers to a person's tendency to convey a certain impression. Some people convey an impression of honesty; others, an impression of dishonesty. Senders convey these impressions to most people in most settings, whether they are lying or telling the truth.

The first evidence of sender demeanor was uncovered in a laboratory study in which participants were videotaped while telling lies and truths. Later, other participants viewed the resulting tapes. They judged which of the earlier participants had been lying and which had been telling the truth. Results showed large differences in sender credibility. Some senders appeared truthful to virtually all the judges, and other senders were almost always judged to be untruthful. Significantly, the senders who appeared most honest when they were lying were the very senders who appeared most honest when telling the truth. The investigators termed this pattern of results a demeanor bias.

A later analysis of results from hundreds of studies attempted to quantify the impact of individual differences on deception judgments. Of several individual differences considered, differences in judgment ability were smallest, and differences in sender demeanor were largest. People differ in the honesty of their demeanor at least 14 times as much as they differ in the ability to detect lies. As these results imply, judges agree on who appears honest and who appears dishonest; they agree even when their judgments are wrong.

Individual differences in apparent honesty are large in every situation in which the differences have been studied. People differ widely in

apparent honesty when they tell motivated lies as well as white lies. They differ widely in apparent honesty when they engage in deceptive interactions and when their honesty is judged from a videotape. They differ widely in apparent honesty when (on average) their lies are detectable and when their lies are not. When Person A judges Person B's truthfulness, the largest single determinant of the judgment is Person B's demeanor, research suggests.

A recent series of experiments underscores the importance of individual differences in apparent honesty. Researchers began by videotaping people who were telling lies and truths, and solicited deception judgments of these videotapes from undergraduates. Using the undergraduates' judgments, they identified the people on the videotape who were perceived as most and least honest. The researchers then created two videotapes: a veracity-matched tape and a veracity-mismatched tape. On the veracity-matched tape were people who appeared honest and were telling the truth as well as people who appeared dishonest and were lying. On the veracity-mismatched tape were people who were telling the truth but appeared dishonest, as well as people who were lying but appeared honest.

The investigators solicited deception judgments to these two specially constructed tapes from a variety of judges: American undergraduates, Koreans, and U.S. government security agents. Without exception, judges were highly accurate in discriminating lies from truths on the veracity-matched tape. Without exception, they were highly inaccurate when judging the veracity-mismatched tape. Deception judgments can be more strongly affected by a sender's apparent truthfulness than the sender's actual truthfulness, as this research dramatically shows.

Researchers have sought to explain why some people appear honest and others appear dishonest. Perhaps people have an honest (or dishonest) demeanor by virtue of the way they talk or certain impressions they convey. Research shows that people who appear honest are those who seem competent and involved in social interactions. People who appear dishonest are those who sound indifferent, uncertain, and ambivalent. Their remarks seem planned and implausible. As conversationalists, they do not place events in context. A person's

apparent honesty does not strongly depend on the person's tendency to make eye contact. This is surprising because a widely held stereotype holds that liars can't look people in the eye.

Judges make inferences about a sender's honesty in different settings. Often, they see and hear the sender in a face-to-face interaction. Sometimes, they hear the sender but are not in a position to see him (or her), as in a telephone call. Still other times, they might need to determine the honesty of a person they have seen but not heard from a soundless videotape. There are still other occasions when deception must be judged from text, as from a written transcript of a sender's remarks.

Do people who appear honest in one communication medium appear honest in another medium? The answer is yes. A recent analysis of multiple studies shows that people who sound honest (in an audio-only medium) look honest (in a video-only medium). Moreover, their remarks appear truthful when read in a transcript. These cross-modal consistencies have not yet been explained. Additional findings suggest that audiovisual impressions of honesty depend more on how a person sounds than how he (or she) looks. The strongest cues to apparent honesty seem to be audible, not visible, these findings suggest. An opposing viewpoint is the video primacy hypothesis that social judgments depend most heavily on what the judge sees.

Laboratory research suggests that it is hard to tell when people are lying. No doubt, there are many obstacles to lie detection. One, however, may be sender demeanor. Many people appear honest, even when they are lying. Others appear dishonest, even when they are telling the truth. Differences in sender demeanor may bias deception judgments. They may bias judgments in the courtroom, where guilty-looking defendants may be sentenced to jail, while those who appear innocent are set free.

Individual differences in apparent honesty might, in principle, be related to differences in the tendency to lie. It is possible, for instance, that the people most likely to avoid lying are those who appear honest. This would be true if others' prophecies of a person's honesty became self-fulfilling. In a relevant investigation, people were encouraged to agree to tell lies for a later study. They were, however, given the option not

to lie. Meanwhile, a facial photograph was taken of each participant. In a later session, people who did not know the participants rated the resulting facial photographs on several dimensions, including the honesty of the person depicted. Results showed that the participants least willing to tell laboratory lies were participants whose facial photographs were perceived as most honest.

If it is true that people who appear honest are unlikely to lie in everyday life, real-world lie detection may be more accurate than laboratory research would suggest. In laboratory research, all participants are required to lie, even those who are truthful in other settings. Outside the laboratory, it is possible that people have a better sense of who is likely (and unlikely) to lie. Further work on this possibility would be welcome.

## Siege of Mafeking

The Siege of Mafeking was a decisive victory for Great Britain during the Boer Wars. The battle endured for 217 days, spanning from October

16, 1899, to May 17, 1900. It took place in and around the city of Mafeking, South Africa, as British forces sought to defend the premises from a Boer invasion. The British army employed a number of deceptive strategies during the siege, which served as a turning point for Great Britain in the war.

The Boer Wars consisted of two wars: the lesser-known First Anglo-Boer War and the Second Boer War. Both wars were fought between the British Empire and Dutch settlers of the South African Republic and the Orange Free State. The First Anglo-Boer War was triggered, in part, by Britain's 1877 annexation of the South African Republic (not to be confused with the present-day Republic of South Africa). After three months of combat, the British government resolved that victory would be too costly and take too long to actualize. A peace treaty was signed on March 6, 1881.

In 1886, however, the Witwatersrand Gold Rush reignited tensions between the British and the Boers, as each side sought control of the lucrative Witwatersrand gold mines. Located 30 miles south of the Boer capital, Witwatersrand contained the largest deposit of gold-bearing ore in the world. Such wealth made it financially viable for Britain to renew its imperial interests in the South African Republic, initiating the Second Boer War.

The Second Boer War began with a pre-emptive attack by the Boers on British-controlled territories in Natal and Cape Colony. Among their pre-emptive strikes was an assault on the city of Mafeking, a clash which would later become known as the Siege of Mafeking. British forces had gathered in Mafeking because of the resources and mobility supplied by its railway junction. They amassed between 1,200 and 2,000 soldiers in preparation to march south. But before they could launch an assault, approximately 6,000 Boers descended upon the town.

Boer forces began their siege of Mafeking on October 13, 1899. Realizing they largely outnumbered the British, the Boers demanded that British forces surrender. When they refused, the Boers began shelling Mafeking with payload-carrying siege mortars. Over the next seven months, the Boers continued their assault on Mafeking, culminating with a final offensive attack on May 12, 1900. The Boers lost more than 100 soldiers

*Lord Frederick Roberts steps onto the gangway upon his arrival at Cape Town, South Africa, to the relief of British troops, who are badly shaken by a succession of defeats. Roberts was instrumental in the victory of the Siege of Mafeking in May 1900, in which the British made skillful use of military deception.*

in the attack (60 dead and 108 imprisoned). In light of their losses, the Boers finally decided that Mafeking was too heavily fortified to seize; they eventually redeployed their forces elsewhere. The 217-day Siege of Mafeking was finally lifted on May 17, 1900, resulting in a British victory.

### **British Deception During the Siege**

Britain's ability to withstand such a prolonged assault from the larger Boer army has been largely attributed to its skillful use of military deception. Deceptive strategies included faux land mines, nonexistent barbed wire, an embellished number of gunners, feigned military confidence, and even cross-dressing soldiers. Early in the battle, British forces supplemented their dwindling artillery by distributing phony land mines along the perimeter of Mafeking, within clear view of Boer forces

and their spies. When moving between trenches located on the edge of town, British soldiers also simulated the presence of nonexistent barbed wire by pretending to duck beneath, climb over, and move between imaginary wire obstacles. An embellished number of gunners were conveyed to the Boers by systematically repositioning artillery and searchlights in order to give the impression that more gunners existed than the British actually possessed.

The Boer army was also deceived and intimidated by Britain's aggressive attack using an armored train. Laden with British sharpshooters, the armored train was sent deep into the Boers' camp. Such an assertive strike, augmented by the train's safe return, led many Boers to overestimate Britain's military strength. Finally, British soldiers were even ordered to dress as women in an effort to deceive the Boers. The cross-dressed soldiers were then directed to carry out everyday tasks within the Boers' range of view, such as washing dirty laundry or stitching with needle and thread. The soldiers' casual performance of such common chores deceived their enemy into thinking conditions were much more desirable within Mafeking than they actually were, thus disheartening the Boer army, whose strategy had been to wait out the British forces.

### **Victory Celebrations**

Prior to Britain's successful defense of Mafeking, the Second Boer War had largely been a disaster for the British army. As news of the victory reached Britain, however, the citizenry was enthused by the Mafeking resistance. Immense, extravagant celebrations erupted in London as citizens learned of the British victory. These celebrations served as the inspiration for the back-formation of the English verb "to maffick," which means to celebrate in a public, extravagant manner.

Sergeant Horace Martineau, Trooper Horace Ramsden, and Captain Charles FitzClarence were awarded Victoria Crosses for their heroic actions during the Siege of Mafeking—the highest military decoration awarded to members of the armed forces of various British Commonwealth/Empire countries. In 1904, under the direction of Lord Frederick Roberts, an obelisk was also erected at Mafeking bearing the names of all those who were killed defending the town.

The greatest honors, however, were reserved for Colonel Robert Baden-Powell. Baden-Powell was promoted to major general, becoming the youngest person in the British army to hold this position. He also was celebrated as a national hero when he returned to Britain in 1903 to serve as inspector general of cavalry. Upon his return to Britain, Baden-Powell learned that his book *Aids of Scouting* had become immensely popular and was being adapted by teachers for children. Building upon his newfound celebrity, Baden-Powell went on to be an instrumental figure in the modern Scout movement by holding scouting camps for young boys and writing *Scouting for Boys*, which modified his previous work for a younger audience.

### Conclusion

The 217-day Siege of Mafeking served as a major turning point for Great Britain during the Second Boer War. In order to guard the city of Mafeking from incursion by a much larger Boer army, the British employed a number of deceptive strategies. Such strategies ranged from faux land mines to nonexistent barbed wire, feigned military confidence to cross-dressing soldiers. Ultimately, their deception proved successful, resulting in spontaneous celebrations (also known as “mafficking”) throughout Britain and a legacy that includes the modern Scout Movement.

## Situational Familiarity

Situational familiarity is defined as a “personal perception of knowledge of a place, task, activity, or topic relevant to a judgmental situation.” For example, police officers could be more or less familiar with the process of an interrogation in general. A judge could also be more or less familiar with a topic or an activity described in a suspects’ alibi. Moreover, judges are sometimes more or less familiar with a place described in a message to be judged. Two types of situational familiarity can be distinguished. First, people can be objectively highly familiar with a place, task, topic, or activity, especially when they have actual, detailed knowledge about the place, task, topic, or activity. Second, people sometimes only feel subjectively highly familiar with a place, task, topic, or activity, but do not have actual knowledge about it.

To test the influence of situational familiarity on the ability to detect deception, judges’ situational familiarity was first measured or manipulated. Next, judges had to classify a number of true and deceptive videotaped messages. For example, in one experiment people had to judge videotaped job interviews of applicants talking truthfully or deceptively about their most recent job. Before people saw and classified the applicants’ messages, situational familiarity was manipulated experimentally. In the high-familiarity condition, judges received additional detailed information about the jobs mentioned in the interviews, whereas in the low-familiarity condition, no such information was given. In another study, the subjective familiarity with interrogations was manipulated with experienced police officers and police trainees. In the high-familiarity condition, police officers and police trainees received feedback that enhanced their perceived situational familiarity. In the control condition, no such positive feedback was given.

In sum, recent research has assumed and found that judges’ situational familiarity could influence the ability to accurately classify true and deceptive messages. Both correlational and experimental studies have found that higher actual or perceived situational familiarity leads to higher classification accuracy when judging true and deceptive messages. For example, police officers’ and lawyers’ self-reported familiarity with police interrogations, in general, or with the specific topic

of the messages to be judged, was found to be positively correlated with the ability to correctly classify true and deceptive accounts. Moreover, experimental research found direct evidence that situational familiarity influences the accuracy to correctly classify truth and deception.

The result that higher situational familiarity leads to better detection of deception was found for different populations (students, experienced police officers, police trainees, lawyers, and law students), with different topics mentioned in the true and deceptive messages to be judged (an alibi in a mock crime, job interviews, driving exams), and with different manipulations of actual or perceived situational familiarity. Overall, higher situational familiarity was found to improve accuracy rates in the range of about 8 percent to 23 percent. Considering the lesser ability of laypersons and experts to detect deception, these are not trivial improvements.

Judges' situational familiarity did not influence the judgmental bias (that is, truth bias). Judges under high or low situational familiarity did not differ in the overall percentage of messages classified as truth.

Interestingly, judges under high situational familiarity reported higher confidence in their decision than judges under low situational familiarity. Most important, the confidence ratings of judges under high situational familiarity were positively correlated with actual classification accuracy. For judges under low situational familiarity, no such positive correlation was found. This better accuracy-confidence calibration of judges under high situational familiarity shows that judges under high situational familiarity are not only better in detecting deception but also have better insight into whether the judgment is correct or not.

### **Influence of Situational Familiarity on Verbal and Nonverbal Cues**

Why does higher situational familiarity improve deception detection accuracy? Situational familiarity influences the type of information people use when making deception judgments. When judges are highly familiar with a situation, they use predominantly verbal content cues (that is, plausibility or detailedness) for their lie/truth judgments. They do not rely strongly on false

stereotypical nonverbal cues (that is, liars avoid eye contact or liars show more arm or leg movements). In contrast, low familiarity leads to the use of more false nonverbal cues when judging the veracity of a statement.

The hypothesis that situational familiarity influences the use of verbal content and stereotypical nonverbal cues was tested and confirmed with different experimental methods. First, some researchers use simulated interviews to manipulate verbal content and stereotypical nonverbal cues in a message. For example, in one study researchers created four versions of a videotaped conversation in which they orthogonally manipulated both stereotypical verbal content and nonverbal cues shown by an actor. The advantage of this procedure is that it provides the opportunity to directly demonstrate judges' use of verbal content and/or nonverbal cues in credibility attribution, but actual accuracy of judgments cannot be tested with this procedure. Researchers also use self-report measures to assess if judges use either verbal or stereotypical nonverbal cues. Finally, the correlations of peoples' judgments with the objective presence of verbal and nonverbal cues were used to investigate the judgmental process.

Research on actual cues to deception has found that verbal content cues are better indicators of actual deception than most of the stereotypical nonverbal cues. Therefore, the strategy of judges under higher familiarity to use more valid verbal content cues and less false stereotypical nonverbal cues leads to better deception detection.

### **Conclusion**

Research on the influence of situational familiarity on veracity judgments has come to the following conclusions: situational familiarity moderates the use of stereotypical nonverbal and verbal content cues, with higher situational familiarity leading to a more pronounced use of verbal cues and less use of stereotypical nonverbal cues. Higher actual and perceived situational familiarity improves the ability to correctly classify true and deceptive messages. Judgments under higher situational familiarity are associated with higher confidence, and these judgments are better calibrated.

## Smoke Screen

A smoke screen is something intended to confuse, obscure, or mislead others. In the original sense, a smoke screen is a dense mass of smoke used to conceal operations or movement from an opponent, traditionally from a military enemy force. The term has also come to be used more generally for the use of other strategies to conceal information or misdirect attention.

Smoke screens can help conceal troop movements, slow attacking forces, disrupt command and control functions, and reduce the vulnerability of significant assets for both friendly and enemy forces. Smoke, as used in this discussion, is an artificially created product produced by burning or vaporizing some substance, which results in particles becoming suspended in air, such that it weakens or blocks a particular part or parts of the electromagnetic spectrum, particularly visible light, infrared light, ultraviolet light, or microwaves. The U.S. military classifies smoke as visual, which obscures visible light; bispectral, which obscures visible through infrared light; multispectral, which obscures visible through millimeter wavelengths; and special purpose smoke, which obscures specifically targeted portions of the electromagnetic spectrum.

### Historical Use of Smoke Screens

Smoke screens have been used as a military tactic since ancient times to confound an enemy by shielding from view an opposing force. In antiquity a simple campfire or smoldering torch could have been used to produce excess smoke. It has been speculated that the fleeing Hebrew people during the Exodus from Egypt were screened by smoke from Pharaoh's forces. There is evidence that military application of smoke by burning damp straw to smoke enemy positions dates back at least as far as 2000 B.C.E.

The U.S. Army experimented with smoke screens during World War I but used them more extensively during the World War II and subsequently. Accordingly, the Chemical Warfare Service was established as part of the American Expeditionary Force in 1918; it became the Chemical Corps in 1946 as a branch of the U.S. Army. Smoke screens were a significant part of the battle arsenal of the Chemical Corps.

During World War I, battleships would deploy smoke screens to conceal their location. One of the best-known instances of the use of this tactic was during the Battle of Jutland on May 31 and June 1, 1916. During World War II, the U.S. Army deployed HC M1 smoke pots in battle situations, such as during the Battle of Monte Cassino in Italy, in which smoke had numerous uses, such as screening ammunition dumps, constructing bridges, in group operations, at river

assault crossings, at supply routes, and in troop concentrations. The U.S. Air Force used smoke to control flights and to mask targets in midair.

Smoke screens have also been used defensively to conceal cities and towns during bombing raids. During World War II, for example, the United Kingdom routinely used smoke screens to protect cities, harbors, and factories from Luftwaffe bombers. The U.S. Navy used smoke screens as protection from air attacks and to otherwise conceal vessels at sea. For example, American naval personnel used M1 mechanical smoke generators to screen Allied ships of the invasion fleet and supply facilities in the port of Bizerte in North Africa on July 7, 1943, such that Nazi pilots could not locate their targets; therefore, the over 3000 bombs dropped all missed their targets and not a single ship was sunk.

Of course, not only the Allies used smoke screens during the World War II. The Japanese forces, for instance, used a Type 100 50-kilogram smoke bomb.

During the Korean War, chemical smoke generation companies were established within the U.S. Army. One Korean battle site became known as Smoke Valley because one of these companies generated smoke 24 hours a day to obscure the North Korean and Chinese forces' visibility of the U.S. Army Tenth Corps. During the Vietnam War, smoke ships were used as part of the Airmobile Concept to protect men on the ground from small-arms fire.

### Modern Use of Smoke Screens

Smoke screens continue to be employed in modern warfare, and an array of technologies is now employed to create varied types of cover. Smoke screens can be generated from canisters, such as by grenade or mortar shell, or deployed by smoke generators, which can be either stationary or placed in vehicles, such as from a tank, ship, or a U.S. Army Humvee. Smoke screens can help conceal troop movements, slow attacking forces, disrupt command and control efforts, and reduce the vulnerability of significant assets for both the friendly and enemy forces.

More sophisticated detection devices have resulted in the evolution of more developed smoke screen technologies as countermeasures. The strategic use of smoke screens is still recognized to

have utility to attack and defeat specific enemy targets and to target acquisition systems, sensors, weapon guidance systems, and other electro-optical devices. Synchronized smoke planning is currently integrated into tactical battle planning. For example, the use of infrared viewers and sensors has led to techniques to screen beyond the visible light spectrum. Similarly, target designators or range finders utilizing laser beams can be thwarted by extra dense forms of smoke with additional types of particulate matter dispersed.

Modern smoke grenades, whether hand-thrown, fired from a rifle (such as the U.S. M19 A1 WP spigot launched grenade), or otherwise projected, are primarily meant to obscure vision, as were their predecessors. However, many smoke grenades now also contain white phosphorus, which also has incendiary and anti-personnel effects. Contemporary hand-thrown examples of white phosphorus smoke grenades include the British No. 80 WP, which is time-fused, and the German DM 19, which has a pull cord arming device and phosphorus filler that detonates as the canister body breaks upon impact with the ground.

The use of smoke screen technologies is not restricted to only military situations. For example, rum runner boats were known to deploy smoke screens during Prohibition in order to evade capture. Currently, police and other law enforcement agencies can deploy smoke screens to assist with riot control and similar activities. It has been known for some time that smoke screens can produce harmful effects to those exposed to the smoke screen material. The inhalation effects of breathing this material can be seriously adverse, including acute inflammatory changes, respiratory distress, pulmonary injuries, and even death.

### The Figurative Smoke Screen

*Smoke screen* is a term that has acquired several different meanings with respect to lying and deception. The original use of the term, of course, was to refer to the use of a dense mass of smoke to impede the visibility of opponents, typically an enemy military force. However, the concept has come to be used to describe other forms of deception. In political campaigns and other public activities, a smoke screen can be an attempt to conceal some embarrassing or scandalous

information; this could serve as a pretense to keep some material secret. In debates or in business marketing programs and other similar dealings, a smoke screen can be used as a red herring thrown up as a distractor; this might be used to grab attention and to serve as bait to attract customers, but the real intent could be to maneuver customers toward another product or service. Similarly, a student taking an examination might submit a vague essay rather than clearly indicate that he or she does not know the correct answer.

## Soccer (Football)

Soccer is one of the oldest and most popular sports in the world. It is played by tens of millions of youth and children in North and South America, Asia, Africa, and Europe. It is gaining popularity in the United States. Today, there are approximately 250 million players officially playing in teams around the world. The World Cup competition, which is held once every four years and includes teams representing between 190 and 200 countries, is watched by billions of people across the world. It is played between two teams,

each with 11 players, and a ball. The aim of the game is to put the ball in the goal at each end. Except for the goalkeeper, players are not allowed to use their hands to hit the ball. The International Federation of Association Football (FIFA) governs the game internationally and organizes the World Cup.

In agreement with several theories in psychology, such as Bandura's social cognitive theory of moral thought and action and Vygotsky's socio-cultural theory, many communities, schools, organizations, and governments use soccer as a way to instill values of honesty, cooperation, respect for the rules, and trust in youth. As in many team sports, trust among players is important, and lying and deception can erode such trust. Even in the countries suffering severe oppression or

Argentina's soccer team captain, Diego Maradona, celebrates their World Cup victory, June 29, 1986. In the quarterfinal between Argentina and England on June 22, Maradona scored one of the most controversial points in World Cup history when he used his hand while pretending to hit the ball with his head. Four years later, he apologized for his comment at the time: "From the hand of God to the head of Maradona."

corruption, soccer provides an opportunity for youth to play by common rules, expecting fairness and that the better team wins. As an opportunity for some form of Freudian catharsis, soccer also provides a nonviolent outlet for hostilities that might exist between communities or countries. Soccer has also been used as a form of therapy to help children suffering consequences of wars or trauma to rebuild their trust in themselves and others. Lying and deception, especially if the victim's story is not believed, can in such circumstances stimulate buried history of psychological hurt. In addition, sometimes perceptions of unfairness or lying and deception might be symptoms of other hidden psychological issues. Many referees are accused of bias by fans, despite a lack of evidence to support such perceptions. Such accusations might reflect a history of trauma or general sense of persecution and oppression.

### Winning by Deception

Even though lying and deception are outlawed in soccer, they are frequently used by players or others in the game. Some players try to deceive referees by breaking the rules when the referees are not looking in their direction. Deception by players can take many different forms, such as touching the ball by hand while playing, physically injuring another players, pretending to be injured to win a foul or to waste time or to cool the other team down. One the most famous examples is when Diego Maradona of Argentina, one of the world's most famous soccer players, scored a goal in the England versus Argentina World Cup quarterfinal game in 1986 by using his hand while pretending to hit the ball with his head. The FIFA rules do not allow the referees to rely on recorded TV images to review the incident, so the goal stood.

Another form of deception by players is the use of banned substances. FIFA has been strictly trying to enforce the banned substances rules for a long time. The FIFA rules punish such behaviors severely if discovered. Players, teams, or anyone affiliated with such behaviors can be given a warning or a fine or can be kicked out of the game or suspended for extended periods.

Sometimes lying and deceptions are undertaken by the referees. Game fixing is a big problem in soccer, in which some players or referees might play in ways or make decisions that will produce

a game with secretly agreed upon results. A player might let the opponent team score a goal, or a referee might make several biased calls in favor of a team. Sometimes, both teams agree to end the game with a certain result that will favor them both at the expense of a third team. Sometimes, powerful forces in society supporting a team, or criminal elements involved in underground betting on game results, try to bribe or threaten players or referees in order to control the outcomes of games. Such perceptions of game fixing can ignite violent reactions by supporters of various teams, also known as football hooliganism. Recently, accusations of lying, deception, bribery, and corruption reached deep into FIFA in regard to how it chooses the host countries for World Cup competitions.

Furthermore, sometimes lying and deception in soccer are done by fans of teams. Some fans, in communities that believe in superstitions, are involved in magic or sorcery in an attempt to influence the outcome of the games. Some might use laser light to blur the vision of players, throw objects at them, or scream racial or other insults in order to influence the game. Some fans might even physically attack, injure, or drug players before, during, or after a game.

### Soccer During Incarceration

Many prisons and jails in the United States and other countries provide some kind of recreational activities, including soccer. These activities are meant to provide inmates with physical, mental, and emotional outlets to enhance their well-being. Soccer and other sports provide constructive ways for inmates to use their spare time while also giving them the skills that may help prevent them from reoffending. When inmates are completely idle, they become bored. They may also feel frustrated or aggressive and become violent toward themselves or others. Soccer can provide a positive way to reduce the stresses of incarceration by providing physical stimulation while teaching team-building skills.

One potential downfall to soccer played in prisons and jails is that lying and deception can occur among the inmate population, by those participating or those observing or refereeing. Because cash and currency are strictly prohibited within the correctional environment, soccer and

other sports can be used as a means of betting and organized gambling. Game fixing by players or inmate referees is one way to sway the outcome of the competition so that the winning team benefits from gaining additional canteen products or winning inmate labor services such as laundry or other cleaning duties. Depending on the race or nationality of the assembled inmates, their allegiance to a particular country or team can also contribute to a climate issue among those participating. Setting aside the downfalls of lying and deception, the benefit of soccer to those incarcerated far out weighs the downside of the sport. Proper supervision of the competition by correctional officials will minimize the risk of gambling and place an emphasis on the physical outlet and team-building skills that soccer can bring.

Several studies examined the psychological correlates of antisocial behavior, such as lying and deception, in soccer. For example, ego orientation was positively correlated to antisocial behavior toward opponents. Further, ego orientation and perceived value of toughness had an indirect positive correlation to antisocial behavior toward opponents. Moral disengagement, as defined by Bandura, was found to mediate between such psychological characteristics and antisocial behavior. In addition, studies found that antisocial behavior ratio to prosocial behavior in soccer increased with age. There were also gender differences in antisocial behavior in soccer, with males engaging in more antisocial behavior than females. Lack of empathy was positively correlated to antisocial behaviors such as lying and deception in soccer.

## Sock Puppetry

Pseudonyms and other false identities have been used for centuries. However, the rise of the Internet has created public forums in which people speak their minds and at the same time wish to remain anonymous. On the Internet, the new form of false identifies is termed *sock puppetry*.

A sock puppet is a false identity used online in order to hide true identity. It is a form of deception. The term *sock puppetry* comes from the use of puppets made from socks. The puppets were characters in some form of "show." On the Internet, the term came to be applied to people who would assume a false identity and then join an Internet group. The term has been extended to include people who use false identities on the Internet in order to deceive others. The deception may be acts which praise, blame, defend, oppose, support, attack, defame, ridicule, or otherwise criticize an individual or an organization.

A pseudonym is a name used to protect an identity. Authors have long used pen names for various reasons. Benjamin Franklin, George Sands, Walt Whitman, Anthony Burgess, and other writers have used pseudonyms. However, a sock puppeteer pretends to be someone who is not a member of a group to which they are really connected. Or, he or she falsely pretends to be sympathetic to

a group in order to be disruptive. Some Internet social communities will expel or block sock puppets when exposed.

The first use of the term *sock puppet* was on July 9, 1993. The term came into general use by 1996. At first, the *Oxford English Dictionary* defined a “sock puppet” as a person who is controlled by someone else. The idea of a sock puppeteer as a minion was an extension of the term that was published in 2000 by *U.S. News and World Report*.

The Internet has created many opportunities for online voting. Unscrupulous people will create sock puppets in order to stuff online ballot boxes. In other cases, a sock puppeteer may create multiple identities to support arguments, voice opinions, or otherwise create the online illusion that many people support the sock puppeteer. This practice is called a “Sybil attack” after Sybil Dorsett, which was a pseudonym for Shirley Ardell Manson, used by Cornelia B. Wilber in her 1973 book, *Sybil*. Wilber, a psychoanalyst, treated “Sybil” for multiple personality disorders. Those who use “Sybil attacks” are using multiple personalities in order to anonymously attack others online.

### Straw Men

Another use of sock puppets is to engage in stealth marketing. Also known as “undercover marketing” or “buzz marketing,” the stealth marketer will create sock puppets in order to create the illusion of genuine allegiance to a product, cause, ideology, or other item that is being sold. The sock puppeteer engaging in stealth marketing is an actor who engages in a confidence game to win people to their product by deceptive means. Critics of stealth marketing call it “roach marketing.” It is a form of guerrilla marketing in which people do not even realize they are being hustled to buy something.

In logic, a straw man argument is an informal fallacy that creates a caricature of an opponent’s argument. The “straw man” is then presented as a faithful representation of an opponent’s position, but because it is a flimsy representation, it is easily defeated or discredited. A straw man sock puppet pretends to be a faithful representation of the teachings, beliefs, ideology, or position of an individual or organization, but the straw man sock puppeteer is really just pretending. It is a form of a false flag (*ruse de guerre*), flown to pretend to be

neutral while hiding one’s true identity as pirates, privateers, or covert military operatives.

The straw man puppeteer pretending to be from the opponent’s side will engage in a manner to discredit that side with behaviors that are bigoted, ignorant, or irrational. They operate in a manner similar to Internet “trolls.” Trolls seek to sow discord on the Internet, confuse with distractions, or to otherwise disrupt the rationality of the group’s communications.

Sock puppet behavior is sometimes described as “meat puppeteering.” A number of online behaviors are described with this term. The behaviors include using blogs or other venues to push a product or interest. The meat puppeteer tries to generate the illusion of interest or a buzz about something using sock puppet identities. The buzz may be enhanced by recruited fellow travelers who promote the goals of the meat puppet with “astroturfing.” This is the practice of hiding the sources behind the sponsors of a message. It is using a front organization that hides the identities of those behind the promotion while concealing the identity of the true sponsors. It makes artificial support look like natural grassroots support for something or some cause.

### Modern Sock Puppets

The use of sock puppetry in the virtual spaces of social media has allowed the unscrupulous to forge their identity, usually multiple times, in order to practice praising or defaming. Sometimes, sock puppeteers engage in Internet vandalism by changing facts or information online. Wikipedia has been open to these attacks.

Ways to identify sock puppeteers are growing. Techniques involve using algorithms that combine analysis of the links used and the style of authorship.

People caught practicing sock puppetry have included Jeremy Trevathan of Pan Macmillan. He and others have been accused of posting book reviews that either exaggerated the worth of books or belittled competitive books.

John Mackey of Whole Foods Market was uncovered as a sock puppeteer after he practiced deceptions online for eight years. He posted messages on Yahoo’s financial message boards praising the stock of Whole Foods Market. He also belittled the worth of competitors, particularly

Wild Oats Market, while engaged in actions to acquire Wild Oats Market at a cheaper price. The discovery of Mackey's over 1,200 sock puppet posts prompted an investigation by the Securities and Exchange Commission (SEC).

Raphael H. Golb, a Chicago real estate lawyer, maliciously created sock puppet accounts in order to attack and discredit biblical scholars who disagreed with his father's theories about the Dead Sea Scrolls. On November 18, 2010, in *New York v. Raphael Golb*, Golb was convicted for his defamatory attacks and for identity theft, criminal impersonation, forgery, aggravated harassment, and unauthorized computer use.

actual argument or presentation. Like many topics of interest in social psychology, inquiry into source credibility has roots in World War II. Led by Carl Hovland and his contemporaries, explorations of source credibility came about because of interest in the construction and effects of propaganda. From the beginning there was an intuition that highly credible sources could be useful in delivering messages focused on persuasion rather than truth. A concern, therefore, is that persons of high credibility may be used to deliver lies or deceptive messages, and that these lies will go undetected.

### The Sleeper Effect

One of the early important findings on source credibility was Hovland's "sleeper effect," which showed that a message from a low-credibility source may become more believable across time as the link between the message and the source fades. This somewhat counterintuitive finding has many practical applications in modern political campaigns, in which unknown (noncredible) political action committees run deceptive ads. According to the sleeper effect, such ads will be persuasive in the long term because their message will remain after its original source is forgotten. Later research suggests that this effect only occurs when the message is persuasive and has an impact over time, the discounting cue is large, and enough time has passed. One way to reduce this deception would be to remind the audience of the low credibility of the original source.

Typically, the impact of source credibility is measured by presenting research subjects with a message given by message communicators of variable credibility. The impact of credibility is measured by changes in subjects' beliefs, behavioral intention, or decision making. A meta-analysis indicated that while source credibility only has a relatively small effect on persuasion (4.5 percent of the variance), the combination of source, message, involvement, and the listener has a larger collective effect.

Source credibility's power is centralized in the communicator-listener interaction. While individual characteristics of the communicator, such as perceived expertise and trustworthiness, have been found to increase source credibility, such characteristics do not exist in a vacuum.

## Source Credibility

Source credibility is the extent to which the communicator of a message is believable; it is distinct from message credibility, which focuses on the

Perceived expertise depends on the message being communicated: the more consonant the message is with characteristics of the communicator, the more expertise will be perceived. For example, a message about the reliability of memory, from a person with published research in the area of memory, would likely be seen as credible.

In turn, the importance of the message is often a function of the listener's involvement in the message: the more identifiable a message is with a trait or concern of the listener, the more the message will be perceived as important. For example, a person with a specific health issue is more likely to listen to messages about that issue than a healthy person would.

### Credibility and Persuasion

Modern inquiry of source credibility also owes a large debt to Richard Petty and John Cacioppo's experiments in the late 20th century on credibility and persuasion. Their work demonstrated that source credibility is most important when listeners either are relatively uninvolved in the message content or unable to process the complexity of it. Conversely, source credibility is least important when listeners are heavily involved in a message, especially one that they perceive they understand well. Additionally, listeners who are presented with a message they disagree with might reject it more vigorously when it comes from a credible source than from a less credible source.

Recent research also indicates that a communicator's source credibility may impact not only the attitudes of a listener but also listener certainty about their attitudes. In fact, Zakary Tormala and Richard Petty found that if a high-credibility communicator fails to persuade a listener, the failure might have a "boomerang" effect—unsuccessful persuasion from a high-credibility source might force the listener to dig in harder against persuasion.

If the listener can detect deception in the communicator, it will undermine source credibility. Deception detection is often studied by exposing research participants to a series of truths and falsehoods. Participants are then asked to make judgments about the truth content of each statement. These answers are then assessed, often using signal detection theory. As such, results can give a complex picture of peoples' abilities: First,

it seems that people are truth-biased, defaulting to expect that others tell the truth. Second, a meta-analysis demonstrated that people, both in the aggregate and individually, are only slightly better than chance (approximately 55 percent) at detecting falsehood. These results stand in stark contrast to people's perception of their own capabilities. The general public believes themselves very capable of detecting deception, and some subgroups, such as police officers, rated themselves as being able to detect falsehood 77 percent of the time.

As noted above, people are poor deception detectors. A recent meta-analysis indicated that there is not a great variability from person to person in terms of ability to detect falsehood. Potential individual-level moderators such as sex, education, intelligence, profession, age, and so on all have negligible-to-zero effects. Message transmission medium (for example, e-mail, person to person, telephonically, and over the Internet) has similarly little impact. In other words, the inability to detect deception may be generalizable to all types of people in all types of settings.

While it is true that some people are regarded as more honest or less honest than others, it has been demonstrated that the more credible a communicator seems, the less likely it is that their message will be heavily scrutinized. It is this lack of scrutiny that allows lies and deception to go unnoticed.

Source credibility and deception interplay in a number of public arenas. For example, Bernie Madoff, architect of one of the biggest financial frauds in U.S. history, used his considerable perceived credibility to lie about complex financial vehicles to a number of clients, investors, and investigators, and he was able to dodge serious inquiry of his misdeeds for over 10 years. Madoff's lie was highly related to his perceived area of expertise, and he has not been able to gain his credibility back.

However, not all losses of credibility that follow lying are irreversible. For example, former president Bill Clinton lied under oath about a sexual affair, and although he did lose credibility, the fact that his area of expertise (politics) is different from the actual domain of the lie likely made it possible for him to regain credibility over time. In addition, Clinton's lie was seen as less damaging

than Madoff's, and thus it was easier to regain credibility.

### Conclusion

High source credibility is an important factor that can lead to deception and lies going undetected. A source is considered credible if he or she is seen as trustworthy and an expert in the domain of the message. People are relatively poor detectors of deception, and is especially true when they pay very little scrutiny to the message, as is the case with messages delivered by highly credible sources.

## Spanish-American Conquests

The Spanish-American Conquests refers to an era initiated by Spanish, Portuguese, and Italian explorers and discoverers of the Americas. As history well demonstrates, there is a very fine and jagged line that separates explorers from conquerors, and it is quite difficult if not impossible to determine at what point the explorer became a conqueror and vice versa. Some of these historical figures/legends include Christopher Columbus, Hernán Cortés, Ferdinand Magellan, Francisco Pizarro, Vasco Núñez de Balboa, Amerigo Vespucci, and Juan Ponce de León.

Seen in this light, 1492 could very well mark the beginning of the conquests. Although Columbus would initially be placed under the rubric of The Age of Discovery and Exploration, it was not long before the admiral became a conqueror/conquistador. The act of enslaving the natives, together with that of taking possession of the Caribbean Islands for the Spanish Crown and renaming them, rendered Columbus a conqueror.

Although many conquerors immediately followed in Columbus's footsteps, one conquistador is emblematic of the conquests and owes much if not all of his success to his cunning: Hernán Cortés, who subjugated the Aztecs and took the territory today known as Mexico for the Spanish Crown. Although Cortés was the winner, and a champion of lying and deception, he was deceived and lied to as well. The cunning and deceit of this conqueror will serve as a paradigm of the lying and deception always evident throughout the Spanish-American Conquests.

### A "True" History of the Conquest of Mexico

Even the telling of the conquests themselves is problematic. In the early 1560s—upon reading the accounts of the conquests written by Francisco López de Gómara—Bernal Díaz del Castillo, a conquistador who participated in the conquest of Mexico, was so appalled by the utter misrepresentation of the Mexican conquest that he decided to write his own account in 1568, which he promised would be truthful and "bring into full light the conquest of New Spain, and of the heroic services of us the true conquerors, who

with our small numbers, under the adventurous and brave Captain Hernando Cortes, and with great danger and hardships, gained to his majesty this rich country.”

In the preface to the *True History of the Conquest of Mexico* (which suggests that there was a false history), Díaz lists several of Gómara's untruths. Many had to do with the exaggerations “of the numbers of the natives, and of those who were killed in the different battles,” thus rendering his account “utterly unworthy of belief.”

Díaz avers that the number of people who were killed never exceeded 400 men, and if it had, the Spanish could not have put them to death: “Alaric a most brave king, and Attila a proud warrior, never killed so many of their foes as were are said by that historian to have done in New Spain.” Díaz also denies having burned many cities and temples and that Cortés gave orders secretly for the destruction of the Cuban governor's ships; Díaz insisted it was done by the common consent of all. Other critical assessments of Gómara's account have to do with his omission of the discovery of Yucatán by Francisco Hernández de Córdoba; the defeat of conquistador Pánfilo de Narváez; the wars of Tlascalala, where he is “as erroneous as ever”; and the war in Mexico, where Gómara treats as a matter of little importance the fact that the Spanish lost over 800 men, makes no mention of further losses in the siege, and “speaks of it as if it had been a festival or a marriage!”

It would appear that even in the telling, untruths that want to pass as truths are continually replacing firmer untruths. The truth of the matter is that everyone who participated in the conquest, or wrote about it, had stakes in the conquest, and therefore had to bend reality in order to secure these stakes. Consequently, the first lie or myth about the Spanish-American Conquests, one that is pertinent to all the different expeditions and the conquerors themselves, is the myth of truth: every single lie claimed to be the truth.

### The Myth of the Conquerors

Another lie or myth tied to the Spanish-American Conquests is that of the conqueror himself. Even during their lifetimes, these conquerors were converted into larger-than-life figures capable of incredible military prowess and superhuman bravery. Hernán Cortés, who was appointed captain

general of the Armada in 1518 by the governor of Cuba, Diego Velasquez, will serve as a paradigm. Although it was most likely that Cortés set out on his expedition with the intent of conquering land west of Cuba, of finding gold, and of subjugating peoples, he assured the governor of Cuba that his journey would prove useful and exploratory.

Although there were some Spanish explorers who had disappeared after a scouting expedition, Cortés's expedition was the opportunity to discover more land and claim it for the governor of Cuba and the Spanish Crown. In fact, Cortés had grown weary of the tedious life in Cuba and tired of being second to the governor; he therefore set out with the intention of defying Velasquez by assuming independent command of the fleet and declaring himself sole conqueror of the land that would soon be known as New Spain. This expedition, therefore, started out as a lie.

The first land spotted was the coast of Yucatán. In a theatrical gesture, Cortés seized upon Captain Pedro Alvarado's pillaging of a native village to reprehend Alvarado, send for the aggrieved natives, return their stolen goods, and send them to tell others of the Spaniards' kindness and generosity.

As Cortés and his men proceeded along the coast, they formed alliances with Mayans who had recently been conquered by the Aztecs, and they collected as much information as possible, making the Mexican ambassadors believe that Cortés was an ambassador himself, full of innocent curiosity and honesty and eager to meet Moctezuma, the Aztecs' leader.

Historians agree that Cortés knew how to stage a theatrical presentation for the maximum effect. For example, in his effort to impress the Mexican ambassadors, he used a snorting stallion as he scented a mare and fired a cannon to blast a tree to suggest supernatural powers. But his deceit was not only aimed at the peoples he was attempting to subjugate; in an effort to evade Velasquez's orders to return to Cuba, Cortés pretended to have burned his ships, when he had in fact grounded them.

### The Myths of La Malinche and Moctezuma

Soon after their arrival, Cortés and his men came across one of the men who had disappeared during the former expedition and enlisted him because he spoke the Mayan language. A few months later,

*In this Mexican mural, Hernán Cortés's arrival in Mexico is depicted as coinciding with the return of the Aztec god Quetzacoatl, which appears as a serpent. La Malinche is shown by his side, managing a network of interpretations between Moctezuma and the Spaniards. Cortés's lying and deception was emblematic of the Spanish-American conquests; however, he was deceived and lied to as well.*

Cortés would receive a woman captive as a gift, one who would become yet another myth, the myth of La Malinche. The chronicles have it that La Malinche was a captive Mayan princess who had learned the language of the Mexicans. The result was a chain of interpreters: Cortés would address the Spaniard who had been a captive of the Mayas in Spanish, this Spaniard would in turn address La Malinche in Mayan, and La Malinche would speak for Cortés to the Mexican ambassadors and ultimately to Moctezuma himself in the language of the Mexicans. Moctezuma, in turn, would address La Malinche, who would address the Spaniards, who would address Cortés. Legend has it that La Malinche was so in love with Cortés that she soon betrayed her own people and learned Spanish in order to help Cortés conquer the city of Mexico.

With the myth of truth, the myth of Cortés, and the myth of La Malinche comes the myth of Moctezuma himself, of his weakness and credulity. There is also the myth that Cortés's arrival coincided with the prediction of the arrival of

the plumed serpent, and that Cortés was immediately considered a god by the native people. It could very well be that the natives believed that the Spaniards' horses and the men riding them were one entity, and Cortés and his men used this to their advantage for as long as they could. The chronicles have it that in his dealings with Moctezuma Cortés continued to pretend to be a friendly ambassador, and that he induced Moctezuma to go to a house where the Spaniards were staying, offering him hospitality, and that Moctezuma was made a prisoner when he entered that house.

### **Cortés, the Pícaro**

Cortés is the archetype, the model representative of what Alexander Blackburn considered to be living in the "age of real heroes such as the conquistadores" when "society was teeming with those for whom heroic grandeur would inevitably and often tragically be denied . . ." But could a heroic Cortés be at the same time considered a marginal being, a trickster, an antihero? Is there a contradiction here? Not in the sense that the

*pícaro* is a persona, and a mask, and not merely, as Blackburn states, a parodistic antihero.

Although science considers species and not individuals to be in competition for a niche, a *pícaro* is an individual caught in a competitive race for a niche. In this race there are models, mimics, and dupes or receivers, and these roles are not written in stone; on the contrary, today's model can be tomorrow's mimic, who is always on the verge of being duped by a new mimic.

As a persona, Cortés was a *pícaro* before reaching the shores of Mexico. As an eternal *buscón*, or searcher-wanderer, it was precisely his picaresque nature that led him away from Spain to Hispaniola, then to Cuba, and then to Mexico away from Velasquez. It was also his picaresque nature that made Cortés write letters to the king of Spain while on his way back to Spain, letters in which he continually justified his disobedience toward Velasquez, who represented the king's power.

An outsider and a survivor who never stops to contemplate or to question, a literary character in his own letters, Cortés was therefore a *pícaro*, similar to the characters in picaresque novels. In fact, Cortés announces both the character and the genre. Otherwise, according to Luis Sáinz de Medrano, "How could we explain the fact that a novelist did not emerge from the conquistadors themselves?"

In the second letter, Cortés writes that he is "crazy enough to go where [he] could not return." Here, the Spanish conquistador is a manipulator who mimics the societal wilderness around him in his effort to adapt, to survive, and to get his way in the end. "With that purpose I set out from the town of Cempoal, which I renamed Sevilla, on the sixteenth of August with fifteen horsemen and three hundred foot soldiers, as well equipped for war as the conditions permitted me to make them," Cortés writes to King Charles V. The year is 1519, and nothing will stop Cortés's onward march toward the unknown. At the frontier of the kingdom of Cempoal, Cortés and his army go through a pass and continue for three days through dry, cold, unfertile desert country.

It was not long before Cortés made enemies and took sides, or at least pretended to take sides. A survivor, the conquistador was loyal to no one but himself. Quick to join the war in this fortress-strewn landscape, Cortés writes, "The next day

I left before dawn by a different route, without being observed . . . I burnt more than ten villages, in one of which there were more than three thousand houses."

Barely any time was wasted adapting to this new place, or being an observer, or a transplant. Cortés immediately seizes upon the animosity and the discord between different villages and sees this as an opportunity for subduing them more quickly. He even interpreted the Gospel message, that every kingdom divided is brought to desolation, to justify his actions: "So I maneuvered one against the other . . . and told each that I held his friendship to be of more worth than the other's." Always convinced that God is more powerful than nature, Cortés does not hesitate to join the natives and to commit to war, in other words, to catapult himself into the heart of the action.

Although Cortés was a *pícaro* before he reached the city of Mexico, it is in the city of Mexico—and at the precise moment that he encountered Moctezuma—that his picaresque nature fully developed, as if the stage had already been set. Thus, some environments are good hosts to *pícaros* and to deceivers, as they are to parasites. According to Michael Serres:

One parasite chases another out. One parasite (static), in the sense that information theory uses the word, chases another, in the anthropological sense. Communication theory is in charge of the system; it can break it down or let it function, depending on the signal. A parasite, physical, acoustic, informational, belonging to order and disorder, a new voice, an important one, in the contrapuntal matrix.

By definition, parasites eat and thrive within the body of their host. In this case Cortés represents two different trophic levels of *pícaros*/parasites on an ecological pyramid, and the city of Mexico became his niche, his host. In his book *Parasite*, Serres dedicates an entire chapter to the picaresque, because the *pícaro* is in fact a parasite: "The parasite invents something new . . . He crosses the exchange, makes it into a diagonal . . . He wants to give his voice for matter, (hot) air for solid, superstructure for infrastructure."

It is interesting to note that in all picaresque novels there is barter. One parasite, for example,

lends his eyes to another parasite, in some cases a blind man in exchange for bread, trading eyes for bread in an eternal game of exchange. In Cortés's case, there was voice, translation, and language in exchange for power.

## Spin, Corporate

Based on the perspectives of many, corporations have been deceiving the public for years through corporate spin. Corporate spin is the process used to subvert the interests of the public in order to further a corporation's interests and to accomplish an organization's desired objectives. The term has long been associated with the work of public relations practitioners, perhaps as the result of historical public relations figures and events including Ivy Ledbetter Lee, the Ludlow Massacre involving the Rockefeller family, and the work of Edward Bernays.

The use of the term *corporate spin* often conjures up negative and seedy images of public relations professionals, who are perceived as fixers, manipulators, or members of a "cleanup" crew. However, public relations advocates argue that their work is by necessity joined with a set of deliberate and intentionally persuasive activities. These activities, they argue, should be visible, should be ethical, and should be coupled with a strict adherence to a code of ethics.

### Lee and Bernays

Ivy Ledbetter Lee, one of America's first corporate public relations professionals, played a key role in what would later become known as corporate spin. A former newspaper man, Lee represented many clients in the early 1900s, disseminating facts and information to the public through cultivating an open relationship with the press. During this time, public relations experts were typically called in to "fix" negative public sentiment about an organization or to garner publicity aligned with an organization's views.

Perhaps the most famous of Lee's corporate spin activities is his representation of the Rockefeller family in a 1914 incident known as the Ludlow Massacre. During a coal miners' strike at the Rockefeller-owned Colorado Fuel and Iron Company in Ludlow, Colorado, 14 individuals were killed by company guards. Among the dead were striking miners, miners' wives, and their children. As the Rockefeller family abdicated any connection to wrongdoing, Lee began defending his client and sharing the "facts" of the massacre with the public. Before the U.S. Federal Commission on Industrial Relations, he asserted that the truth

was open to public interpretation, and he propagated facts through the eyes of the Rockefeller family rather than offering an accurate, objective chronicling or an honest depiction of the family's activities. Lee's ability to disseminate facts to the public with minimal concern for ethics, little regard for the public interest, and a maximum concern for representing his client laid the foundations for what would later become known as corporate spin.

If Lee is thought to have initiated corporate spin, many would argue that Edwards Bernays perfected it. Through representing numerous corporate clients in more than six decades of counseling on public relations activities, Bernays is often credited as being both the father of public relations and the father of spin. In service to his clients and their interests, Bernays implemented unprecedented public relations campaigns. He sold Ivory Soap by offering soap sculpture contests. He increased bacon sales by having physicians recommend a daily "American" breakfast that included bacon on behalf of the Beechnut Packing Company, a bacon producer, and he created a worldwide celebration of the electric light bulb called Light's Golden Jubilee on behalf of General Electric Corporation.

Bernays is perhaps best known for his campaign on behalf of the American Tobacco Company, where he was successful at persuading women's rights advocates to hold up Lucky Strike cigarettes as symbols of their freedom in a *Torches of Freedom* campaign. This was accomplished at a time when cigarette smoking was taboo for sophisticated women. Along with charting a direct path to the desired objectives of major corporations, Bernays served as public relations counsel to U.S. presidents, countries, associations, and governmental agencies.

Though regarded as corporate spin and underhanded activity by many, the work of Bernays, the nephew of Sigmund Freud, may best be characterized as using social science research to directly influence the forces that shape public interest, rather than to directly promote products, positions, issues, or movements. In this way, public consent was secured through indirect influence. Individuals were led toward a particular cause, were persuaded to agree with it, and then accepted the idea as if it were of their own origination. For

example, rather than focus on selling pianos, the idea of music rooms in homes became a symbol associated with the elite of society, who would need to purchase a piano to avoid having an empty music room. Rather than a promotional focus on selling cigarettes to women, having the choice to light up became a symbol of female liberty.

Influencing the forces that culminate in the desire for a product or in the consent to a focal activity became the hallmark of Bernays's work as public relations counsel. These activities, referred to as a process of engineering consent, were viewed by many as corporate spin or elitist activities. However, an alternative explanation is that proven research on persuasive strategies was used to influence human behavior and to sway the public's opinion in such a way that the idea originated with the public.

### Modern Use of Corporate Spin

Generally, corporate spin activities continue to be employed in organizations, especially when the systematic intent is to deceive the public. Concealing the harmful ingredients present in food products that permit a corporation to save money, diminishing the negative health implications of poor factory working conditions, and downplaying the detrimental effects of environmental emissions as part of community relations efforts all represent the unethical efforts of corporations to subvert the public good and accomplish their own desired outcomes through corporate spin.

In addition, front-group stealth campaigns are conducted on behalf of corporate partners. These front groups have deceptive names like National Wetlands Coalition (NWC) or Citizens for Better Medicare (CBM) in an effort to disguise their genuine interests. On the surface, front groups are not linked to their corporate partners. However, upon further investigation, the groups founded to preserve U.S. wetlands and reduce drug prices under Medicare actually oppose government intervention to accomplish these outcomes, and they are supported by prominent corporate sponsors like Exxon-Mobil (linked to NWC) and Merck Pharmaceutical (linked to CBM), which are both companies who benefit from the front-group stealth campaign efforts. By acting invisibly with the use of behind-the-scenes coalitions, corporations can wield their influence on public thought and

on lawmakers' thinking with the ultimate aim of impacting legislation to protect their own private interests.

Along with front-group stealth activity, corporations have greater access to media at a time in which fewer sanctions on lobbying efforts and campaign contributions exist. This, too, further positions the public relations profession to potentially have a greater impact on undermining rather than on advancing democratic values.

### In Defense of Public Relations

The negative connotation of corporate spin, along with the serious ethical issues concerning public relations, prompted practitioners in the field of public relations to actively engage in overcoming the negative perception of their work. The largest professional association of public relations practitioners, the Public Relations Society of America (PRSA), established a Member Code of Ethics to demonstrate its commitment to ethical practices, and to emphasize member adherence to professional values such as honesty, fairness, and loyalty in serving the public interest. Though the tactics of public relations, like third-party endorsements or advocacy advertising, continue to be used by practitioners, deception and outright coercion are deemed unacceptable activities for those who adhere to the PRSA code of ethics. Additionally, the use of front groups is a violation of the PRSA code, which specifically identifies front-group activity as an example of improper conduct.

In response to critics who relegate public relations activities to the practice of merely creating and implementing corporate spin, public relations practitioners have offered multiple arguments in their defense. First, public relations involves a broader set of strategic communication functions aimed at both internal and external publics, including issues management, employee relations, investor relations, integrated marketing communications, community relations, and a host of other important organizational functions along with publicity. Second, public relations activities depend on the mutual adjustment of corporate and public interests rather than a rigid insistence on public manipulation. By researching public opinion, corporations are better able to design specific message strategies that are most likely to resonate with a particular public. Through

strategic efforts, the corporation adjusts to fit the public rather than attempt to align the public's view with the corporation.

A final consideration in defense of public relations activities is that persuasion is an integral part of a corporation's strategic communication efforts. Corporations are consistently engaged in assessing the attitudes, issues, and values of the public in an effort aimed at creating, shaping, influencing, or maintaining public consent. Though inherently persuasive, public relations activities are deemed to be a routine and natural component of an organization's relationship with the public and of a thriving democracy. As long as public relations activities remain visible, and the agents fully disclose their involvement and desired outcomes, public relations activities fall within the scope of accepted symbolic activity. In fact, public relations professionals argue that organizations with strong reputations and favorable organizational images are those who link corporate desires with societal interests rather than risk being exposed for violating public confidence.

### Conclusion

The term *corporate spin* continues to describe the deceptive and unethical activities associated with subverting the public good in order to benefit the private interests of corporations. Influenced by the work of early public relations practitioners, corporate spin can range in outcomes from altering, creating, or maintaining an organization's or individual's image to casting a different light on a series of events, a product, a cause, or a movement. To combat the negative associations of corporate spin and similar unethical practices, the PRSA promotes strict adherence to a Member Code of Ethics, in which deceptive activities, such as front groups, have been identified as improper conduct.

## Spin, Political

Political spin is the practice of deceptively publicizing favorable interpretations to explain politicians' words or actions and to create a desirable impression of them, or to explain the statements and actions of political entities, such as party organizations, interest groups, and political action committees. Research by E. M. Stark has shown that spin can make a losing candidate into an electoral victor; researchers Michael Norton and George Goethals found weaker but significant effects. Yet, spin, from its formal recognition in the late 1980s, has received almost no peer-reviewed, scientific study. Most noteworthy about spin is that, even though the target audience (TA) knows spin is deceptive, biased information, delivered by a biased source, regarding an event or utterance that the TA has eyewitnessed, it can, nonetheless, affect the audience's opinions of both candidate and debate, and it can persuade.

### Context

The provider of spin is often a surrogate for a political candidate and is known in the vernacular as a spin doctor; however, a candidate may provide self-spin.

Although spin is often delivered to appear as ad-libbed and conversational, spin is systematically conceived to maximize effectiveness. Spin statements range from having biased, misleading, and selective use of facts, to employing well-established and highly effective propaganda techniques that intentionally exploit a TA's psychological vulnerabilities. Spin's key characteristic is deceptiveness.

There are several types of spin as formally defined, and the nature of spin has evolved from a postdebate phenomenon during the Bush-Dukakis 1988 presidential election, to the current, culturally embedded idea of spin to mean a deceptive, self-serving explanation, usually in reaction to a politician's gaffe.

Following each Bush-Dukakis debate, each campaign's spin doctors gathered in large rooms or halls known as spin alley so that the press could report on each campaign's spin on the debate. Initially, spin sessions like these were televised, but by the 2004 election, most of the major networks stopped covering them because they felt they had little news value. However, spin sessions are now accessible through social media.

Of particular interest when considering political spin are two of its aforementioned aspects: (1) the spin doctor is most always known to the TA as a biased source lacking in the authority and credibility typically characteristic of the persuasive source and (2) spin can be persuasive even though the target audience has eyewitnessed the activity or event that the spin doctor is spinning about, that is, the TA can evaluate the veridicality of the spin doctor's statements (and thus pay no attention to it) because they can make their own judgment about the event in question.)

### The Nature of Spin Content

Most fundamentally, spin content (or spin) can be conceived as the dissemination of one-sided, biased, deceptive conclusions, or a form of white propaganda in which the identity of the propagandist (spin doctor) is known, as are his or her intentions. Most concretely, in the televised debate context, spin is the answers to television interview

*Republican presidential candidates face off during the Iowa GOP/Fox News Debates at Stephens Auditorium in Ames, Iowa, August 11, 2011: from left, former Massachusetts Governor Mitt Romney, Minnesota Representative Michele Bachmann, and former Minnesota Governor Tim Pawlenty. In the televised debate context, spin consists of answers to interview questions posed by journalists. They are seldom direct answers and focus on interpretations and praise of the candidate as well as criticism of the opposition candidate.*

questions posed by journalists. They are seldom direct answers and often bear no relationship to the questions that elicited them. Generally, spin is interpretations, conclusions, and repetitive praise of the candidate, and criticism, warranted or not, of the opposition candidate.

As mentioned, and from a psychological perspective, spin is often laden with schemata to lessen the cognitive miser's workload. Schemata allow the subject to make rapid inferences with little effort and reach conclusions without assiduously and diligently examining the information at hand. Many types of schemata exist, among them political schemata. One example might include, "She is card-carrying member of the NRA." Such a statement affects the TA by providing a single piece of content that allows them to infer a wealth of information about the candidate with little cognitive expenditure.

Richard Lau offered a model of political cognition in which voters evaluate candidates using

four schemata: issues, group affiliations, party identification, and personality. For many people, a candidate's party affiliation alone will determine the resonance of their conclusions about the spin doctor's statements. For other, uninvolved debate viewers, attending to superficial characteristics related to the candidate's personality will serve the same function. Each of these cases refers to viewers who are cognitive misers.

Spin statements are also well stocked with common propaganda techniques found in publicly available copies of the Army Psychological Operations Field Manual. Such techniques include the bandwagon effect. This is essentially communicating to the TA that the vast majority of people will vote for the candidate or think favorably about him or her, which exerts social pressure on the TA to join the crowd.

Another common technique is glittering generalities. This is the practice of heaping lavish praise on the candidate for his or her debate performance.

Such praise or statements might be, for example, “He did fantastic tonight,” or “He was presidential,” or “Tonight you saw a wonderfully competent performance by candidate Jones.”

### Characteristics of the Spin Doctor

The first component of effective spin under normal circumstances of social influence ought to be that the spin doctor—he or she who delivers the spin—would have high source credibility in order to be persuasive. However, as another departure from normal social-psychological thinking about influence, this is not true in the case of spin.

Source credibility typically accrues from the spin doctor having expertise related to the subject at hand, perhaps a good, well-established reputation, and a modicum of attractiveness. A good example of credible sources are commentators who are Nobel laureates and have no pecuniary or other interest in the subject matter upon which they are commenting. They are thus expert and unbiased and trustworthy. A good example of a nonexpert but credible source would be the then highly popular and late baseball player Joe DiMaggio, who was a pitchman for the Mr. Coffee brand of coffee makers. DiMaggio was not a coffee expert, beyond, perhaps, his knowledge of his own taste preferences. However, he had a long-established reputation among the greater public of being trustworthy, so in his case, expertise was not a variable that figured into his credibility.

What makes spin doctors as sources a special case within an influence paradigm is that in almost all circumstances, they are known as biased sources of information. In fact, in the context of televised candidates’ debates, spin doctors are identified as workers or surrogates for the particular candidate they represent. As such, one might expect that the TA would pay no attention to their utterances. The TA’s expectation would be that the spin doctors’ statements would be uninformative, because by nature they would reflect only positively on the candidates whom they represent. Moreover, because the TA has viewed the debate for themselves, they have good reason to completely disregard the spin doctors’ statements. But this is not the case.

As one example, the uninvolved TA is by nature tasked with reaching a conclusion about the debate they have just witnessed. They must do

so with an information deficit. Moreover, the TA hears not only favorable interpretations and conclusions regarding a candidate but also negative interpretations and conclusions about the opposing candidate. As a cognitive miser, the availability of such conclusions lightens their cognitive workload.

### The Psychology of Spin

One formulation, verified by research conducted by the author, is that the TA comprises of a gamut of people, most of whom are cognitive misers. This is to say that people, tasked daily with making a large quantity of judgments, conclusions, and decisions, and perhaps lacking the ability, resources, interest, and time to engage in effortful thinking, seek to reduce their cognitive workload by using shortcuts or heuristics, a hypothesis first put forth in detail by Amos Tversky and Daniel Kahneman. The spin doctor, aware of this, provides carefully considered conclusions about the event the TA has witnessed for themselves, and this relieves them of the task of thinking for themselves.

Moreover, to make the cognitive workload even lighter, the spin is laden with schemata, which have the powerful property of allowing the TA to go beyond the information given and easily make inferences. For example, if a spin doctor characterizes an opposition pro-choice comment as that of a baby killer, the TA can draw many vivid conclusions about the character of the candidate.

Richard Petty and John Cacioppo have made a distinction between heuristic and effortful thinking, which they term peripheral versus central cognition, and several other researchers have developed similar formations with different formulations, such as Shelly Chaiken’s systematic versus heuristic formulation. These models have several implications for spin and when and under what conditions it will be effective.

Making the assumption that people are cognitive misers, the following would obtain: When the TA is uninvolved or uninterested, the stimulus (debate) is complex and difficult to process, the TA has little time in which to do the processing, and the postdebate spin is laden with schemata that allow the TA to make inferences well beyond what is stated, the spin will evoke unsystematic, uneffortful processing of the spin

(little thinking about it), and it will be effective. When the TA is involved, the debate issues matter a great deal to them, the debate itself is not complex and taxing of thought, they have plenty of time to think things over, and the spin is not laden with schemata, then the spin will be ineffective. (See Figure 1.)

**Figure 1** Conditions under which peripheral and systematic processing occur.

Source: Dr. Evan Mitchell Stark

### Contemporary Spin

Spin has evolved far from its narrow meaning related to televised debates. Contemporarily, it is well embedded in the lexicon of the culture and is meant to mean any deceptive explanation given for a transgression, usually political, and usually in the form of a statement. An example would be when a U.S. Senate candidate made a comment about women and rape: "What I understand from doctors is that it's really rare—if it's a legitimate rape, the female body has ways to try to shut that whole thing down."

This comment generated a firestorm of negative reaction, which required a corrective spin, also known as "walking back" the statement. To do so, the candidate subsequently said the following:

In reviewing my off-the-cuff remarks, it's clear that I misspoke in this interview and it does not reflect the deep empathy I hold for the thousands of women who are raped and abused every year. Those who perpetrate these crimes are the lowest of the low in our society and their victims will have no stronger advocate in the Senate to help ensure they have the justice they deserve.

Notice how the spin attributes the misstatement not to ignorance of female reproduction but instead speaks of "off-the-cuff remarks."

## Stalin, Josef

Josef Vissarionovich Stalin was born on December 18, 1878, in Georgia, then part of the Russian empire. As a Bolshevik revolutionary, he played an active role in the Russian Revolution of 1917 that toppled the czarist regime. In 1922, he was appointed general secretary of the Communist Party's Central Committee. In 1924, Stalin successfully navigated the power vacuum created by Vladimir Lenin's death, effectively becoming the leader of the Soviet Union. He continued to serve as such until his death on March 5, 1953. In an effort to soften his harsh image, Stalin deliberately cultivated an avuncular public persona. He was informally referred to as Uncle Joe, affectionately by his friends and admirers and ironically by adversaries as well those uncomfortably allied with him.

Stalin was a master of Machiavellian machination. He seized leadership of the Soviet Union, and kept it, by ruthlessly purging the Communist Party—and the nation as a whole—of any potential opponents. Those who posed actual or perceived threats to Stalin were eliminated in a variety of ways. Some were falsely charged as "enemies of the state" and then executed, exiled, or imprisoned in the labor camps of the infamous Gulag. Others were covertly assassinated, with their deaths faked to look accidental.

Such was the case with Solomon Mikhoels, artistic director of the Moscow State Jewish Theater. Despite Mikhoels's additional service as chair of the Jewish Anti-Fascist Committee during World War II, an increasingly anti-Semitic Stalin ordered him killed. The murder was made to look like the result of a car accident by having a truck run over Mikhoels's already dead body, which was then deposited in a snowbank beside a street in Minsk. To keep up appearances, Mikhoels was given a state funeral.

Stalin's opponents disappeared in others ways as well. Official photographs were doctored to eliminate images of those who had fallen out of favor with him. Not even high-ranking Soviet officials or close friends of Stalin were immune from such treatment, as the cases of Nikolai Yezhov and Leon Trotsky illustrate.

As People's Commissar for State Security, Yezhov was head of the NKVD (the Soviet Union's secret police). From 1936 to 1938 he was the point man for Stalin's Great Purge, which targeted a wide swath of Soviet citizens, ranging from humble peasants to the powerful and privileged, millions of whom were killed. As an unintended consequence, the Great Purge diminished the nation's agricultural, industrial, and military capacity, leaving the Soviet Union ill-prepared to face the threat posed by Nazi Germany. Yezhov's efforts earned him the same treatment, with Stalin's approval, that he had inflicted upon others. In 1940, he was arrested, tortured, and forced to confess to crimes against the state, for which he was executed.

Trotsky suffered a similar fall from favor. Despite his credentials as a leading Communist theorist and his service as the Red Army's founder and first leader, he was assassinated in Mexico on orders from Stalin. After their deaths, Yezhov and Trotsky were conspicuously absent from official photographs in which they had previously appeared, often in close proximity to Stalin. Such positioning was an unambiguous sign of the status they once enjoyed as members of his inner circle.

### Duplicity in International Relationships

Duplicity played a significant role in Stalin's relationships with other countries. In August 1939, the Soviet Union and Germany signed a nonaggression treaty, the Molotov-Ribbentrop Pact. As part of a secret protocol, the two powers connived to divide eastern Europe into Soviet and German spheres of influence, sealing the fate of Poland, the Baltic states, and other peoples and regions. Neither Stalin nor Adolf Hitler abided by their agreements, and by June 1941 their two countries were at war with one another, with Stalin allying the Soviet Union with Germany's enemies.

Toward the end of the war, in 1945, Stalin met at Yalta with Prime Minister Winston Churchill of Great Britain and the United States' ailing leader,

President Franklin Delano Roosevelt, to discuss details concerning the conclusion of the war in Europe and the geopolitical reorganization of the continent once Nazi Germany had been defeated. Immediately after World War II, Stalin broke with the Western allies and failed to live up to what he had agreed upon, such as free elections in Poland. Consequently, Europe was effectively divided into two opposing camps by a boundary Churchill called the Iron Curtain, and it remained divided until the end of the Cold War in 1991.

Many of Stalin's lies have lived on long after his death, and some have continued to shape internal policy and international relations. A particularly instructive example is the cover-up of the March 1940 Katyn forest massacre of approximately 22,000 captured Polish officers.

When Prime Minister Władysław Sikorski, head of the Polish government in exile, asked about the missing officers, Stalin assured him that they had been freed. The massacre came to light when, in 1943, German soldiers discovered the mass graves. The Germans, however, were conveniently blamed for the atrocity by the Soviet government. This scapegoating continued until 1990, when the Soviets finally admitted culpability.

The crime continues to be a divisive issue in Polish-Russian relations, with disagreements about declassifying documents and whether to define the massacre as merely a political crime or an act of genocide. Today, there are still Stalinist apologists who maintain his innocence regarding Katyn, as well as other atrocities committed during his tenure as the leader of the Soviet Union.

## Statement Validity Assessment

Statement validity assessment (SVA) is a verbal veracity tool designed to determine the credibility of child witnesses' testimonies in trials for sexual offenses. SVAs are accepted as evidence in some North American courts and in criminal courts in several western European countries. The tool originates from Sweden and Germany and comprises four stages. Much of the research concentrates on the third stage, criteria-based content analysis.

### Stage 1: A Case-File Analysis

The case-file analysis should include information about the child witness (age, cognitive abilities, relationship to the accused person); the nature of the event in question; and previous statements of the child and other parties involved. This gives the SVA expert insight into what may have happened and the issues under dispute. The three subsequent stages focus on these disputed elements.

### Stage 2: The Interview

In the interview the child provides his or her own account of the allegation. Interviewing young children is difficult because their descriptions of past events are notably incomplete. Special interview techniques based upon psychological principles have been designed to obtain as much information as possible from interviewees in a free narrative style.

### Stage 3: Criteria-Based Content Analysis

Criteria-based content analysis (CBCA) is a systematic analysis of the child's statement (which is transcribed for this purpose). CBCA consists of 19 criteria that are thought to be more frequently present in truthful than in fabricated statements. Examples of these criteria are: unstructured production (whether the information is not provided in a chronological time sequence); contextual embeddings (references to time and space: "He approached me for the first time in the garden during the summer holidays"); descriptions of interactions (statements that interlink at least two actors with each other: "The moment my mother came into the room, he stopped smiling"); and reproduction of speech (speech in its original

form: “And then he asked: ‘Is that your coat?’”). These criteria are more likely to occur in truthful statements because it is thought to be cognitively too difficult for liars to fabricate them.

Other criteria are more likely to occur in truthful statements for motivational reasons. Liars cannot take their credibility for granted and are concerned with making a credible impression on the interviewer. Liars are therefore keen to leave out information they believe will sound suspicious. As a result, a truthful statement is more likely to contain information that people may think sounds suspicious, such as spontaneous corrections (corrections made without prompting from the interviewer: “He wore a black jacket, no sorry, it was blue”) and raising doubts about one’s own testimony (anticipated objections against the veracity of one’s own testimony: “I know this all sounds really odd”).

#### Stage 4: The Validity Checklist

CBCA scores may be affected by factors other than the veracity of the statement. Stage 4 of the SVA method is to examine whether there are any alternative explanations that may have affected the CBCA scores. The Validity Checklist comprises 11 issues that are thought to possibly affect CBCA scores. One issue is inappropriateness of affect. This refers to whether the affect displayed by the child when being interviewed (usually via nonverbal behavior) is inappropriate for the child’s alleged experiences.

A second issue is appropriateness of language and knowledge. It refers to whether the child’s use of language and display of knowledge is beyond the normal capacity of a person of his or her age. When this occurs, it may indicate the influence of other people in preparing the statement. A third issue is whether the child demonstrates any susceptibility to suggestion during the interview. Suggestible children may be inclined to provide information that confirms the interviewer’s expectations but is, in fact, inaccurate.

#### Research and Evaluation

Despite being used as evidence in courts, it is unclear how accurate SVAs are because no reliable data in real-life cases are available. To examine the accuracy of SVA in real-life cases it is necessary to know what truly happened in the disputed

event. This can only be determined via case facts (for example, medical evidence) that indisputably link, or do not link, the alleged perpetrator to the crime. Such case facts are often not present in sexual abuse cases.

CBCA has been evaluated almost exclusively by laboratory experiments. In these studies, occasionally children, but usually adults, took part, but the studies showed similar results for children and adults. In alignment with the CBCA assumption, many CBCA criteria were more often present in truthful statements than in fabricated reports, and 73 percent of the truths and 72 percent of the lies were correctly classified using CBCA assessments.

There are reasons to believe that applying the Validity Checklist is sometimes problematic. The justification of some issues listed on the Validity Checklist could be questioned, such as displaying inappropriate affect during the interview. It implies that “appropriate affect” exists, whereas it does not. Some sexually abused victims express distress that is clearly visible to outsiders, while others appear numbed and cues of distress are not clearly visible. The communication styles represent a personality factor.

Other issues, such as susceptibility to suggestion, are difficult to measure. To measure susceptibility it is recommended to ask the witness a few leading questions. Interviewers should, however, only ask questions about irrelevant peripheral information, because asking questions about central information could damage the quality of the statement. Being restricted to asking questions about peripheral information is problematic, as this information may say little about the witness’ suggestibility regarding central parts of the event. Children show more resistance to suggestibility for central parts than peripheral parts of an event.

Determining the exact impact of issues is also difficult. For example, in one study SVA raters were instructed to “take into account” (in an unspecified way) the age of the child when calculating CBCA scores. Nevertheless, several criteria positively correlated with age.

Given these difficulties with the Validity Checklist, it is not surprising that if two experts disagree about the truthfulness of a statement in a German criminal case, they typically disagree about the likely impact of Validity Checklist issues on that statement. A Swedish field study revealed

that experts sometimes use the Validity Checklist incorrectly as a result of difficulties in applying it. For example, the study highlights the influence of Validity Checklist issues on children's statements in general, but fails to discuss how these issues have influenced the statement under investigation.

### Conclusion

Although SVA assessments are used as evidence in criminal courts to evaluate the veracity of child witnesses' testimonies in trials for sexual offenses, the accuracy of these assessments is unknown. Research has shown that CBCA-trained evaluators make mistakes in classifying truth-tellers and liars and that the use of the Validity Checklist is problematic.

## Stewart, Martha

Martha Stewart, a self-made billionaire, a former stockbroker, and one of the most well-known women in the United States, was imprisoned in 2004 for insider trading in the stock of biopharmaceutical company ImClone Systems. A federal grand jury in New York City and the Securities and Exchange Commission (SEC) had filed nine charges against Stewart, and a jury found her guilty on four counts of obstructing justice and lying to investigators. She was sentenced to five months in prison.

### Before the Scandal

Stewart was born in Jersey City, New Jersey, to middle-class Polish Americans Edward and Martha (Ruszkowski) Kostyra. She was the second of six children. Growing up, her mother taught Stewart how to cook and sew, while her father had a passion for gardening, teaching Stewart his expertise. After high school, Stewart attended Barnard College, where she met future husband Andrew Stewart, a recent graduate of Yale Law School. They married in 1961, and eventually had a daughter, Alexis. Stewart returned to college, graduating with a double major in history and architectural history.

The couple moved to Westport, Connecticut, where Martha began a catering business. In 1977, Andrew became the president of Harry N. Abrams, a prominent publisher of high-quality art and illustrated books. Martha's company was hired to cater the book release party of the blockbuster success *The Secret Book of Gnomes*, resulting in her encounter with Alan Mirken of the Crown Publishing Group. This chance meeting led to Mirken personally contacting Stewart to write a cookbook that would feature recipes and photos from parties and would showcase Stewart's talents for catering events. On December 13, 1982, *Entertaining* hit the bookstores, becoming a huge success and leading to Stewart's many other books. Andrew and Martha's marriage was less successful, ending in a divorce in 1987.

In 1990, Stewart began her magazine *Martha Stewart Living*, serving as editor in chief; the publication's circulation peaked in 2002 at more than two million copies per issue. Stewart also began a weekly 30-minute television spot for her

magazine, showcasing her talents for homemakers. This program expanded into an hour week-day format and half-hour episodes on the weekends and led to her position as a contributor on CBS's *The Early Show*.

In 1997, Stewart created a business empire after securing funds with the assistance of business partner Sharon Patrick. Stewart was able to purchase ventures related to the Martha Stewart brand, consolidating them into one company named Martha Stewart Living Omnimedia (MSLO). That same year, Stewart announced the launch of the companion Web site to *Martha Stewart Living*, a catalog business, and a floral business. The control of this empire was in the hands of Patrick, who was named the chief of operations of MSLO, with Stewart as chairperson, president, and chief executive office. Stewart became the first female, self-made billionaire in the United States on October 19, 1999, when her company went public on the New York Stock Exchange.

*Martha Stewart at the Time 100, an event publicizing Time magazine's published list of the 100 most influential people in the world, May 4, 2010. Stewart gradually rose back up the ranks of popularity after her 2004 conviction for insider trading.*

### Insider Trading Scandal

According to court documents, Stewart was flying to Mexico with two friends on December 27, 2001, when she checked her messages, including one from her stockbroker Peter Bacanovic. He informed her that ImClone stock had dropped below \$60 a share. Stewart received this message a day before the Food and Drug Administration (FDA) refused to review ImClone's cancer drug. Stewart, to this day, insists that a stop-loss order was issued to sell her ImClone stock if it fell below \$60 per share.

In response to her broker's message, Stewart called Bacanovic to sell her 3,928 shares and also called her friend Samuel Waksal. Additionally, Bacanovic transferred \$4.9 million in stock to the account of Waksal's daughter Aliza, who requested that Bacanovic sell \$2.5 million of her own ImClone stock. However, Merrill Lynch blocked the shares Waksal attempted to sell and the stocks he had transferred to his daughter. ImClone's stock price tumbled after the announcement of the FDA's refusal to review the cancer drug Erbitux.

On June 12, 2002, Waksal was arrested and charged with insider trading, obstruction of justice, bank fraud, and previously filed securities and perjury charges. For nine months he claimed his innocence before pleading guilty to insider trading and to six of the 13 charges. Waksal was sentenced to seven years in prison and was released after five years. On October 2, 2002, Douglas Faneuil, the broker's assistant who handled the sale of Stewart's ImClone stock, pled guilty to a misdemeanor charge. He was fined \$2,000 and was fired by Merrill Lynch. The following day, Stewart resigned from her board membership on the New York Stock Exchange.

During the investigation of her alleged wrongdoing, Stewart denied that she engaged in improper trading. Stewart and her broker, Bacanovic, could not provide evidence that a stop-loss order existed. Furthermore, investigators for the House of Representatives' Energy and Commerce Committee could not find any credible record. The SEC was ready to file a civil securities fraud suit, but prosecutors could not prove that Stewart had made a deceptive statement in attempts to repair her credibility. Thus, the five counts against Stewart that were related to the SEC were thrown out.

On March 5, 2004, a jury found Stewart guilty on four counts of obstructing justice and lying to the investigators. Stewart's fate was sealed after the jury heard the damaging testimony of her friend Mariana Pasternak. She revealed on the witness stand that Stewart said, "Isn't it nice to have brokers who will tell you these things." Stewart was sentenced to five months in prison, two years of supervised release, along with a fine of \$30,000. Stewart continues to maintain her innocence and, ironically, if she had sold her stock on December 31 instead of December 27, she would have collected a profit of \$180,000 (\$48,000 less than she gained earlier) without raising concerns. Bacanovic was convicted on all but one charge, making a false statement. He was fired from Merrill Lynch for declining to cooperate with investigators looking into ImClone's stock trading activity.

### After the Scandal

Stewart is one of the few major businesspeople who have successfully rebuilt their companies and regained trust and popularity after a highly publicized scandal. To date, Martha Stewart Living Omnimedia is making a comeback, partnering with other companies, such as E. & J. Gallo Vintage Wines, KB Home, and Macy's, and publishing another best-selling book titled *Dinner at Home*. Stewart continues to control 50 percent of MSLO's stock and 90 percent of voting stock. Although MSLO has taken a huge hit since her incarceration, this decline does not compare to more recent scandals by companies such as Lehman Brothers Holdings, Inc. and Countrywide Financial Corporation. Stewart's conviction shows that no one is immune from the penalties of misconduct.

## Stylometry

Stylometry is the study of text from a linguistic perspective in order to determine its authenticity and authorship. Stylometry is typically applied to written language; however, its techniques have also been used for music and fine art.

One of the earliest known examples of analyzing a text for its authenticity came during the mid-15th century. In 1439, an Italian Catholic priest named Lorenzo Valla analyzed the Donation of Constantine, an alleged decree by Constantine I through which authority over Rome and the Western Roman Empire was conferred to Pope Sylvester I.

Within his work *De Falso Credita et Ementita Constantini Donatione Declamatio*, Valla showed that the donation was a forgery by studying its use of the Latin language. Not only were there discrepancies within the text, but also such terms as *fief* were inconsistent with the form of Latin used at the time of its supposed authorship. Reginald Pecocke, a Catholic bishop of Chichester, later reached the same independent conclusion as Valla. The donation's falsification was finally confirmed when Caesar Baronius, an Italian cardinal, admitted that it was a forgery within *Annales Ecclesiastici*, published during the late 16th century.

Stylometry gained further popularity among linguistic scholars during the 1800s in an effort to determine authorship of certain English Renaissance dramas. These efforts were met with mixed results, however, prompting Wincenty Lutoslawski to outline the foundations of modern

stylometry in *Principes de Stylométrie*, published in 1890. Lutoslawski's text delineated several stylometric techniques that have since become characteristic of the practice.

### Techniques of Stylometry

One such technique is referred to as "author invariant." Author invariant refers to the properties of a text that are consistent with the known texts of one author and inconsistent with known texts of other authors. Common properties that are analyzed using this technique are distribution of word length, average word length, average sentence length, vocabulary richness, functional word frequency, and the use of specific function words. Linguistic scholars, for example, will often work to determine the 50 most common words within a text. They will then divide the text into 2,000- to 10,000-word segments in order to reveal the regularity of those 50 words within each segment. The results can be used to compare two literary works in order to show whether they were written by the same author.

Three additional techniques of stylometry are "rare pairs," "neural networks," and "genetic algorithms." The rare pairs technique analyzes instances of author collocation (that is, sequences of word pairs that co-occur more often than normal within a certain author's writing). There are six common forms of collocation: adjective-noun, noun-noun, verb-noun, adverb-adjective, verb-prepositional phrase, and verb-adverb. Not unlike author invariant, a text's authenticity and/or authorship can be determined by identifying rare pairs that are consistent with the known texts of one author and inconsistent with the known texts of other authors.

Both neural networks and genetic algorithms rely heavily upon computer-mediated software. Neural networks traditionally refer to a circuit of biological neurons: nerve cells that transmit information via chemical and electrical signals. Within the context of stylometry, however, neural networks refer to a training set of desired output(s) that are learned from a multitude of inputs. Referred to as the "backward propagation of errors"—or "backpropagation" this learned training set allows a neural network to approximate new information, thus determining a text's authorship and/or authenticity.

Finally, genetic algorithms use a set of superimposed rules or limitations to determine a text's authorship. One such rule could be "If the word *that* appears more than 2.4 times per 1,000 words, then the text is not by Author X." This set of rules evolves over time, trending toward satisfactory results. It is tested against a known text, revised and modified until it is able to correctly determine authorship.

### Applications of Stylometry

Since its conception, stylometry has been applied to a variety of prominent texts, ranging from the collected works of William Shakespeare to books of the Bible to the *Federalist* papers. Doubts about the authorship of manuscripts attributed to Shakespeare began during the mid-19th century. The most popular speculation of Shakespeare's authorship is the Oxfordian theory, which proposes that works traditionally attributed to Shakespeare were actually written by Edward de Vere, the 17th Earl of Oxford. The Oxfordian theory of Shakespearean authorship is based in part upon author invariants and rare pairs found within Oxford's biography and the plays of Shakespeare. Although this theory persists in some circles, it is largely dismissed by academics and historians.

Stylometric techniques have also been applied to the Bible for centuries. Scholars most commonly focus on the first five books of the Bible, collectively referred to as the Torah or the Five Books of Moses. Philosophers such as Thomas Hobbes and Baruch Spinoza first argued in the 17th century that Moses could not have authored the Torah. Despite an overwhelming consensus among contemporary scholars, many Christians continue to oppose Hobbes and Spinoza, arguing in favor of Moses's authorship.

Stylometry has played a role in judicial history as well. The *Federalist* papers consist of 85 essays that were anonymously published in 1787, in an effort to support the ratification of the U.S. Constitution. Following the death of Alexander Hamilton in 1804, a list was revealed that claimed he had authored 63 of the *Federalist* papers, with James Madison and John Jay authoring the remaining 22. In 1944, however, Douglass Adair analyzed the texts in order to determine their true authorship. He concluded that Hamilton had only written 51 of the essays; Madison had written 26

of the essays; Jay had written five of the essays; the three remaining essays were the result of collaboration. Adair's findings were confirmed in 1964 via computer analysis.

### Conclusion

Although the roots of stylometry can be traced to the mid-15th century and the work of Lorenzo Valla, it gained a foothold in academia during the 1800s. Since that time, a number of stylometric techniques have become standard: author invariant, rare pairs, neural networks, and genetic algorithms. Stylometry has also been applied to a range of prominent texts, evidencing its continued relevance and validity.

## Sun Tzu

*The Art of War* is a Chinese treatise assembled two millennium ago addressing war strategy for battle and invasion. The work has generally been in its complete form since the Han dynasty (approximately 200 B.C.E.), and was probably written between 500 and 300 B.C.E. during the Warring

States period of ancient China. It is attributed to Sun Tzu (Master Sun), a military official, and consists of 13 sections associated with war and battle. Along with Sun Tzu's statements on battle and strategy, 11 commentators provide additional information on the various topics covered. These individual commentaries were added to Sun Tzu's statements sometime between 155 and 1300 C.E.

Section 1, "Strategic Assessments," contains strategies for deception. Though Sun Tzu made only three broad comments regarding deception, much of the strategies on deception in *The Art of War* come from the commentators addressing Sun Tzu's statements (this is also true across all the sections). Sun Tzu states that: "A military operation involves deception. Even though you are competent, appear to be incompetent. Though effective, appear to be ineffective." Mei Yaochen, commenting on Sun Tzu's statement, observes, "Without deception you cannot carry out strategy, without strategy you cannot control the opponent." Another commentator, Wang Xi, addresses Sun Tzu's statement by noting, "Deception is for the purpose of seeking victory over an enemy; to command a group requires truthfulness."

The comments regarding deception in *The Art of War* maintain that deception is not only acceptable but also a required element of military strategy. In particular, an army should appear "opposite" of what it really is. If strong, it should appear weak; if orderly, it should appear disorderly. In essence, one's military goals should include altering the perception of one's enemies.

Other portions of the treatise also mention forms of deception and altering perceptions. Though these comments are not as well known, they do underscore the importance of creating misperceptions to the enemy and even to one's own troops. Section 5, "Force," notes that unorthodox attacks are preferred and that, "victory is gained by surprise." In Section 6, "Emptiness and Fullness," Master Sun states, "Appear where they cannot go, head for where they least expect you."

In Section 7, "Armed Struggle," he states, "So a military force is established by deception, mobilized by gain, and adapted by division and combination." A commentator, Du Mu, then adds, "A military force is established by deception in the sense that you deceive enemies so that they do not know your real condition, and then can establish

supremacy.” Section 11, “Nine Grounds” focuses on leaders being deceptive to their troops, because revealed plans are often discussed, and troops will notice changes in a leaders’ day-to-day routine and anticipate plans. Master Sun states, “The business of the general is quiet and secret, fair and orderly . . . he can keep the soldiers unaware, make them ignorant.”

In terms of knowing when one is being deceived, the last section of *The Art of War* addresses spies (Section 13, “The Use of Spies”). Spies act to provide correct information, therefore foiling deceptive practices by an enemy. Master Sun notes, “Foreknowledge cannot be gotten from ghosts and spirits, cannot be had by analogy, cannot be found out by calculation. It must be obtained from people, people who know the conditions of the enemy.” In other words, foreknowledge is obtained from spies. Because deception is part of warfare, developing ways to see through deception, such as the use of spies is paramount.

### Wide-Ranging Impact

*The Art of War* has been referenced thousands of times across the world in terms of military strategy and politics. But its impact is more wide-ranging, with its messages spread beyond military applications into the areas of psychology, business, economics, history, education, and a host of other fields. Research on perceptions and misperceptions (whether intended or not) is a well-traveled area in psychology research. Sun Tzu’s point is that to directly deceive allows one to gain an advantage over an enemy. Though for Westerners

such prevarications may seem foreign and even immoral beyond wartime, east Asian cultures sometimes see such practices as advantageous and even protective. This may be interpreted as collectivism fully realized, with in-group member needs and rewards taking hierarchy over the out-group. Further, in military application, controlling perception is paramount for success.

## Tall Tales

Tall tales are stories that feature larger-than-life characters and grossly exaggerated situations. Tall tales are deliberate “whoppers,” filled with hyperbole, that purposefully call attention to their outrageously implausible elements, which are conventionally related in a matter-of-fact fashion that suggest they are true. The more preposterous these tales, the better. In this respect, they are unlike the narratives of other fictional genres—such as fables and fairy tales, fantasy and science fiction, horror and urban legends—which include characters and events that challenge credibility, but which still invite their audiences to suspend disbelief.

Tall tales are included in the oral traditions of cultures throughout history and around the world, and their protagonists are consequently diverse: African shamans, Arabic merchants, Hasidic rabbis, Hindu adepts, Native American warriors, Taoist immortals, and Zen Buddhist monks, among others. In the United States, the protagonists are typically members of the working class, rather than affluent members of society, reflecting perhaps traditional American cultural ambivalence toward the wealthy. Like urban legends, tall tales are now disseminated not only from person to person but also via the mass and social media. In this way their narratives spread

further and faster than was possible when they were exclusively shared via oral transmission.

The characters populating tall tales are most often fictive inventions, but some are based on real people—such as Johnny Appleseed, Daniel Boone, Davey Crockett, or Calamity Jane—who have story cycles that include, and often mix, established history and dubious legend with the hyperbolic elements associated with tall tales. At times it is difficult to separate fact from fiction in tall tales that feature historical figures. Some tale tales might better be regarded as legends, which may or may not be true but the veracity of which it is impossible to definitively confirm or deny. Such is the case with a tale told about Cornelius Darnell, a companion of Daniel Boone, who is reported to have jumped across a gorge and over the Little Miami River in order to elude capture by Shawnees, from whom he had escaped. The gorge, located near Yellow Springs, Ohio, is narrow where Darnell is said to have made his legendary leap, with a span of approximately 20 feet. While it is not probable that he leaped that distance, it is possible, especially given his incentive to do so.

Many of the heroes of American tall tales represent occupational types and/or regional identities. They reflect in a highly exaggerated way the aspirations and life experience of cowboys, lumberjacks, sailors, soldiers, and other manual

laborers, as well as eccentrics like Johnny Appleseed who fit no standard occupational category. In doing so, they reflect and reaffirm shared communal values, such as hard work, physical strength, cleverness, and courage. These heroes do things bigger and better than is possible in “real life,” and their possessions are equally supersized.

A classic example is Alfred Bulltop (Old) Stormalong, a ship’s captain who stood six fathoms (36 feet) tall, and whose vast vessel, the *Courser*, had masts so high they were hinged so that they could be lowered in order to avoid hitting the sun or moon. He once saved ships and their sailors by lifting them out of the ocean by himself and placing them onto his own giant ship during a hurricane. Another tall tale hero, Pecos Bill, is a cowboy from Texas who once lassoed a large tornado, which he rode like a big bucking bronco. The force of the water that poured out of the tornado as it tried to throw him is said to have carved out the Grand Canyon. Tall tales of this

kind provide a humorous explanation for the origin of important geographic landmarks.

Old Stormalong’s story illustrates the willingness of one sailor to help others during times of danger, while Pecos Bill’s demonstrates the dogged determination a good cowboy needs to succeed. While many heroes of tall tales conform to and support the values of the established order, some rebel against social norms, as Calamity Jane does in challenging the received view regarding gender roles.

Of all the American tall tales, perhaps none is more popular or better known than those featuring Paul Bunyan, a literally larger-than-life lumberjack, and his companion Babe the Blue Ox, also of gigantic dimensions. There is some dispute as to whether Bunyan’s origins can be traced to anonymous oral folk traditions, or whether his narrative is an example of what folklorist Richard M. Dorson calls “fakelore” (pseudofolklore created by authors who strive to make their stories

Statues of the legendary lumberjack Paul Bunyan and his faithful blue ox Babe tower over visitors to the Trees of Mystery roadside attraction in Klamath, California. The legend of Paul Bunyan is perhaps one of the best-known American tall tales. The origins of the story are somewhat unclear, having come from either anonymous oral tradition or what folklorist Richard M. Dorson calls “fakelore.”

appear to be authentic products of a living folk tradition rather than their own creation).

There is no disputing, however, that Paul Bunyan as he is known today is based upon a series of newspaper stories that appeared in 1906, written by James MacGillivray, a reporter for the *Oscoda Press* in Oscoda, Michigan. In 1922, William B. Laughead, an advertising manager for the Red River Lumber Company, adapted these and other Paul Bunyan stories and included them in illustrated pamphlets that promoted his company and popularized the giant lumberjack. Thanks to his giant size and great strength, Paul Bunyan could outperform any other lumberman. Like Pecos Bill, he is said to have left his mark upon the American landscape, leveling whole forests and creating the Great Lakes, the Grand Canyon, Mount Hood, and other American landmarks.

As cultural products, newly minted tall tales reflect current concerns, and older stories continue to voice those of previous generations. The story of John Henry illustrates the tension between manual work and the machines that displaced such labor during the Industrial Revolution. An African American, John Henry was a freed slave who worked for the Chesapeake and Ohio Railway as a steel driver. This was hard physical labor, requiring great strength and much skill. The introduction of a steam driver to the site where John Henry worked threatened to replace him and his fellow workers. To prove human superiority to machines and save the steel drivers' jobs, John Henry challenged the steam-powered machine to a contest in which he outperformed it. After doing so he collapsed from the strain and died. The Big Bend railroad tunnel near Talcott, West Virginia, is purported to be the place where this heroic contest occurred, although historians, such as Scott Reynolds Nelson, dispute this claim. Still, a marker near the tunnel references the legend, and the town holds an annual festival commemorating it.

Tall tales do more than merely entertain. They reflect and perpetuate cultural values, offer social critique, and voice concerns and complaints. Tall tales are not relics from the past but continue to play a prominent role in contemporary popular culture, where they are recycled through comic books, cartoons, feature films, fine and folk art, songs, television series, and Web sites. They are

also associated with such cultural fixtures and geographic features as local festivals, historical plaques, kitschy roadside art, monumental memorial sculptures, and theme campgrounds. In this way, tall tales enable communities to define themselves by shaping their present and celebrating their past, both the real past and the imaginary.

## Terrorism

Terrorism describes a consistent use of terror in order to create a state of fear that often implies the use of violence and coercion. The United Nations in 1994 defined terrorism as the following:

Criminal acts intended or calculated to provoke a state of terror in the general public, a group of persons or particular persons for political purposes are in any circumstance unjustifiable, whatever the considerations of a political, philosophical, ideological, racial, ethnic, religious or any other nature that may be invoked to justify them.

However, the term has not reached a definitional consent among the international community because its attribution heavily depends on

whose point of view is being addressed. In fact, almost all aspects of the word are subject to disputations: terrorism may be considered as a crime or a moral duty, an offensive or a defensive strategy, asymmetric warfare for small organizations or the enterprise of state actors.

One of the reasons that possibly explain the difficulty in providing an analytic definition of terrorism is that its meaning is also discussed differently in overlapping and competing arenas of public discourse. In the academic field, scholars attempt to find a useful operational definition of terrorism for their research; in the context of the state, statements about terrorism are expressed in the forms of laws, judicial rulings, and regulations; in the public discourse, mediated by means of communication, terrorism tends to be dramatized; finally, in the marginal discourse of groups supporting political violence, terrorism is framed as a necessity, a last recourse, or a desirable form of social action.

There are still common traits in the numerous existing definitions: Terrorism is about politics, violence, and fear. However, the three elements seem to always overlap each other because one of the main analytical difficulties consists of not only clearly distinguishing between the political and the criminal dimension of terrorism but also between politics and violence. Politics, understood as an open competition for the acquisition, maintenance, and expansion of state power, may comprise elements such as violence and coercion, allegedly characterizing terrorism. In fact, it could be argued that in contemporary societies both consent and coercion represent a *conditio sine qua non* for the emergence, establishment, and reproduction of political power. The concept “hegemony,” for example, comprises both aspects.

### Political Aspects of Terrorism

Regardless of its unclear semantic boundaries, terrorism is certainly political in both form and content. Content-wise, terrorism, like war, frequently wants to accomplish political objectives. Not accidentally, many terrorist groups organize themselves as political parties in order to represent their political interests in institutional politics. Form-wise, terrorism is in itself eminently political because of the particular use of violence.

First, terrorists very often adopt political violence in order to politically challenge the monopoly of violence constituted by the state. Furthermore, many terrorist organizations consider political violence as propaganda by the deed or armed propaganda, according to which violence becomes the most rhetorically eloquent political communication.

Political violence, as an inherent characteristic of terrorism, leads to another characteristic: terrorism is designed to produce terror, physical, and psychological fears. Fear is indeed another quality which can be defined as political. Terrorism becomes a fundamental element of the “politics of fear” of both terrorist and counterterrorist strategies. In fact, if violence is political in its challenge of the Weberian definition of the state, fear, as apprehension and a sense of the unsafe, is political in its challenge of the modern contractualist understanding of the state (that is, the state as a social pacification project emerging from a common agreement among its citizens) and the disruption of an economic system funded on the systematic calculations of risks. Thus, terrorism becomes a political tool to dispute the validity of modernity projects of pacification in societies: the state and the civil society.

Finally, terrorism frequently tends to be configured as an asymmetrical conflict between state and nonstate actors. Confirming such an account, Mahatma Gandhi once said that “Terrorism and deception are weapons not of the strong, but of the weak.” In addition, such an asymmetry, understood in political, institutional, and material terms, leads to a political economy of terrorism: because terrorists habitually have less available resources compared to their opponents, terrorist acts are rarely redundant as they tend to economize/maximize the impact of a given action. For this reason, terrorism tends to codify its message into highly symbolic terms, in which the symbolism does not only directly present its message but also represents its mediacy by allegoric language.

### Terrorism as Communication

Given such an excursus about the complexity and multifaceted nature of the definition of terrorism, lying and deception may become important assets of predominately nonstate actors in order to guarantee their safety as combatants operating in the

enemy territory. Furthermore, deception is frequently used in order maintain the element of surprise. Deception and lying used by nonstate actors are mostly utilized to gain tactical and strategic advantage over the enemy. In *The Art of War*, Sun Tzu clarifies the importance of deception by saying that “All warfare is based on deception” and goes on to explain that “. . . when able to attack, we must seem unable; when using our forces, we must seem inactive; when we are near, we must make the enemy believe we are far away; when far away, we must make him believe we are near.”

Framed as an act of high symbolic and communicative value, terrorism can be seen more explicitly connected to lying and deception. Certainly, the relationship between the three terms is a complex and extremely problematic one because of both the ideological and moral charge of terrorism but also because of the ideological and moral charge of deceptive behavior. Terrorism, lying, and deception are frequently associated in the mediated collective perception but their link is not self-evident. When terrorism is used in its pejorative sense (as criminal, immoral, illegal), lying and deception are easily included in its semantic field as criminal and clandestine gestures that misinform through their propaganda.

When terrorism is understood as a communicative practice, lying and deception assume a preponderant role in pursuing terrorist activities. Terrorism can almost systematically be interpreted as a rhetorical situation with a message producer—the terrorist—with a specific means of communications—the source/act of terror—and an audience—both the possible victims and the larger public formed by civil society and the state. Lying and deceptive communication can be operative at all levels of communication, the message production, message dissemination, and message reception.

The link between terrorism and communication seems to be a foundational one and could be traced back to the origin of the modern form of terrorism in the 19th century, when terrorism was known as “propaganda by the deed.” The idea was that spectacular social events could be performed in the public, and therefore could capture the general attention and penetrate the collective mind. Several radical groups of the 1970s, such as the Italian Red Brigades, the German Red

Army Faction, the Uruguayan Tupamaros, and the North American Weather Underground, colloquially known as Weathermen, were involved in what they defined as “armed propaganda.”

Such propaganda had the objective to disseminate their ideas and beliefs but also to fight against the allegedly deceptive lies and information manipulation of mainstream media and news agencies controlled by their opponents. For instance, the 1970s Italian radical group Red Brigades understood part of their agencies as a sort of investigative journalism that would bring to the public eye the lies of the state and its alleged servers.

### Mainstream Media and Terrorists

Mainstream media and terrorist media outlets frequently enter into a rhetorical competition in framing events and unveiling the opponent’s alleged lies. In such competitions, lying and deception become one of the most important fields of contention, as media outlets of opposing parties (that is, terrorist versus state) could reciprocally accuse each other of manipulating the reporting of a given event, such as a terrorist attempt, according to their political agenda. So, for example, on the one hand, mainstream media could be accused by terrorist media outlets of lying in order to manipulate the original message of the terrorist group and to be servile to an equally secretive and deceptive political power. On the other hand, terrorist media outlets could be accused by mainstream media of distorting events because of the overwhelming ideological mediation of the terrorist groups.

The confrontation between mainstream media and terrorist groups in terms of accusation of deceptive behavior may be explained at several levels. First of all, mainstream media would tend to attack the terrorist message based on a dominant sense of morality, legality, and/or ideological principles distinct from the ones of the terrorist group. Second, the media, as economic subjects seeking profit, could establish an ambiguous relationship with terrorism: on one hand, opportunistically, terrorism can become an extremely powerful source of a new event; on the other hand, terrorists tend to behave as powerful ideological state apparatuses, framing nonstate actors and the state in simplistic narratives of villains and heroes. Therefore, the tendency of treating terrorism as

a source of newsworthiness may push the media toward an objective (as supposed to subjective) deceptive process that manipulates terrorism events and transforms them into news stories, therefore highly spectacular and highly simplified.

### Private and Public Spheres

Understanding terrorism as communication also allows one to conceptualize the link to deception through the concept of private and public spheres. As already mentioned, in the public sphere, when a terrorist act is performed in public and under the public eye, deception can occur at the level of production of the terrorist message, at the level of mediation of the terrorist message, and at the level of reception of the terrorist message. The message itself could be considered as deceiving because of the political economy of terrorism, which tends to maximize the (communicative) impact of a given terrorist act. In other words, a group involved in asymmetric warfare, with considerably less resources than its opponent (for example, non-state actors versus state) is not directly connected to the ultimate objective of the given terrorist group, but instead stands as a symbol or a particularly eloquent exemplification.

For instance, when a given terrorist group hits a soldier, a police officer, or a politician, frequently the indirect and more important target of the act was what such a figure represents in the management of a given social order. Thus, the strategic maximization of the impact of a given terrorist act may produce dialectical outcomes: On the one hand, it tends to codify the message in effective and powerful symbols, which, like an image, could speak a thousand words; on the other hand, the symbolic codification of the terrorist act may result in a deceiving and misleading kind of communication process in which the “audience” could misunderstand what the real targets and objectives of the given terrorist group are.

Still, terrorism seen from a public eye may provide occasions for the audience’s self-deception. Because of the remarkable semantic weight of the label terrorism, which flattens and simplifies the understanding of a given phenomenon, the moralized and paradigmatic approaches that understand terrorism as the prototype of a Manichean confrontation between “good” and “evil,” “us” and “them,” are frequently self-deceiving. The

self-deception takes place because, given a will to comprehend a social phenomenon, a moral judgment superimposes a rational/analytic one. In fact, recalling the problem of definitions previously mentioned, and the importance of whose perspective is addressed, from the point of view of an organization militant, the very term “terrorism” may represent a lie, a deceptive representation of a belligerent confrontation whose political value is deprived.

In the private sphere, in the intimate understating of his or her role as a terrorist, or inside the organization, terrorism may be interpreted as a self-deceptive practice. There is an important body of literature that points out how frequently the radicalization and the exceptional internalization of a given ideology may de facto produce a deceptive understanding of reality. For instance, the deceptive force of a deeply internalized ideology may provoke a schizophrenic detachment between the actual reality and the reality understood by that specific worldview. The (self-) deceptive capabilities of ideological mediations also may constitute a fundamental element that guarantees the internal cohesion of the terrorist group, its organizations, and its shared objectives.

### Conclusion

The meaning of the word *terrorism* is highly affected by the rhetoric and politics that surround it. Depending on the point of view represented, the terrorist can be framed as the most dangerous criminal or a national hero, and can be identified as an organization or even a state. Because of its polysemic and contested nature, the word *terrorism* also makes the relationship with deception and lying rather complex. One productive approach that allows some clarification of such a relationship is to treat terrorism as a communicative situation.

Terrorism as communication illuminates the rhetorical confrontation between opposing actors and between opposing, potentially deceptive propagandas. In such a context lying and deception become instruments of rhetorical confrontation competing to frame the meaning of events (such as terroristic attempts). According to such a perspective even the term *terrorism* itself may be considered as the successful achievement of rhetoric that deceives the public by constructing simplistic

binary oppositions, such as political/criminal, legal/illegal, and good /bad. The role of ideology mediating both the perpetration of terrorist acts and the evaluation of such acts may also produce occasions for self-deception.

## Theory of Mind

Researchers have argued that a central cognitive process of deception is the ability to consider and make inferences about the mental states of others, including the beliefs, intentions, and knowledge that another may possess. Such an ability is commonly referred to as a "theory of mind." In having a theory of mind, others' mental states have causal consequences on one's own thinking and behavior; in turn, others' mental states can be directly influenced. This distinction between what one and another know allows deceivers to elicit false realities in the minds of others. However, such explicit mental state reasoning may also enact considerable cognitive costs. Given the ease in which people lie, and the real-time demands of communication, an explicit monitoring of what another knows, or is likely to believe, may be unnecessarily demanding for a liar. Very young children and nonhuman animals are capable of misleading behavior despite the lack of sophisticated mental state reasoning capabilities. Thus, deception may only require a more implicit form of belief reasoning that involves simple belief attributions and perspective taking. Consideration will be given to this relationship between deception and theory of mind by touching on issues in evolutionary theory, cognitive development, and adult social interactions.

### Evolutionary Emergence

Strategic deception is uniquely human, insofar that other species are thought to lack the capacity to model the mental states of conspecifics. Nevertheless, some nonhuman primates and birds (for example, corvids) have been documented as engaging in tactical forms of deception. The nature of such deception mostly involves information concealment rather than actively attempting to instill false beliefs in another. For example, corvids routinely cache (hide) food in one location in the presence of a competitor and will then recache in a new location when the competitor has moved. Such forms of deception suggest a sophisticated ability to navigate complex social environments and seem to require an understanding that, at the very least, others have unique visual perspectives and goals. It has been suggested that such actions correspond to precursors for theory

of mind reasoning, but others caution that such findings only demonstrate learned behavioral contingencies or rudimentary social reasoning and, as such, do not warrant claims of explicit mental state awareness.

### Developmental Considerations

The area in which deception and theory of mind has been most widely explored is that of child development. A great deal of focus has been on whether children's emerging propensities for deception, as well as the complexity of their lies, are related to their development of theory of mind. Existing evidence suggests that children's ability to engage in deception is directly related to the degree to which they understand that others are able to see something they cannot see (first level), to understanding the thoughts of others and possible inferences that can be drawn from this understanding (second level).

To evaluate various levels of belief reasoning, researchers typically employ tasks that examine children's abilities to attribute false beliefs to another. A common example is with an "unexpected change" scenario. Children are given a story in which a character witnesses an object being placed in a box. This person leaves the room, at which time the object is switched to a new location. When the main character reenters the room, children are asked where they think the person will go to retrieve the object. If a child understands that the person has a false belief about the object's location (because the person was absent when the object was switched), the child should indicate the original location. Many versions of this and similar tasks have been developed, varying in terms of the memory and language demands needed to complete the task, as well as the complexity of the mental states that need to be considered.

Studies suggest that over the course of development, as children tell lies of increasing difficulty, their ability to reason about others' mental states also becomes more sophisticated. Thus, children as young as 2 years of age may be able to engage in simple forms of deception (for example, denial), but their lies are also expected to be limited and lacking in variation. It is not until a sophisticated theory of mind is developed, around 3 or 4 years of age, that children are able to tell more complex

lies. As converging evidence for the central role of theory of mind, children who have autism, a condition associated with the inability to access and reason about the mental states of others, are suspected to have considerable difficulty with deception at all ages.

Although a theory of mind appears necessary for deception, there are also significant challenges to this view. One source of conflicting evidence is that children as young as 15 months old, who are unable to pass rudimentary false belief tests, are still able to lie. This has raised the question whether very young children are actually engaging in intentional deception. Rather, they may be responding in such a way that expresses a desire for how things ought to be. For example, when a young child breaks a toy and is asked who did it, an answer of "nobody" may reflect wishful thinking. For responses that are less ambiguous, such as "I don't know" or "the cat," these lies also may not count as genuine cases of intentional deception. Theory of mind advocates have argued that such responses arise from learned behavior-response contingencies that are tied to limited contexts. As a result, lies told by very young children should be highly predictable.

However, recent evidence suggests otherwise. With evidence drawn from naturalistic contexts, the range and types of lies told by young children are seemingly complex. One reason for this complexity is that the observed lies occur in communicative interactions, in which simple attributes about another's knowledge are easily realized. Merely being questioned ("why is the toy broken?") suggests a lack of knowledge by the speaker and an opportunity for the child to provide information that serves their own needs (avoid punishment). Explicit reasoning about another's mental states may not be necessary. Ongoing evidence from the interaction, in how a caregiver responds or behaves, provides further opportunities that allow the child to maintain or expand on their deception. Thus, deception may be a communicative act that is similar to any other type of information the child wants to express.

Other studies that challenge the role of explicit theory of mind are those that dissociate mental state reasoning from the ability to lie. For example, researchers have compared the deception aptitude of children who show delays in mental state

reasoning with those who show no delays. Important for analysis, the groups are otherwise equivalent, including on measures of general intelligence and demographics. The reason that one group of children shows specific delays is that they were born deaf and therefore have not yet mastered certain language skills that are hypothesized to be critical for a theory of mind. These skills include the use of mental state verbs and certain syntactical structures for expressing propositional attitudes (for example, “The girl believed that he was going to the store”). As expected, compared to the hearing group, the deaf children performed poorly on the false belief tests yet showed no differences with the hearing children in understanding and employing deception.

### Adult Social Interactions

According to impression management theories, deceivers typically monitor the linguistic and nonverbal behavior of others for signs of suspicion. This requires an awareness of the social impressions that they are having on others. Presumably, this also requires an understanding that others’ also possess and are drawing from a theory of mind that is unique from that of the deceiver. To prevent suspicion, as any good poker player can attest, deceivers need to act or speak in such a way that conforms to what others are likely to perceive as being honest.

In studies examining the neural processes involved in impression management during deception, distinct brain regions, such as the right temporoparietal junction (RTPJ), tend to show greater activation. This region is also involved in nondeceptive tasks in which people must predict and explain the behaviors of others based on what they might believe. However, RTPJ activation is not solely dedicated to theory of mind processing, as it is also implicated in what is known as attentional reorienting. Such domain-general processes may thus support theory of mind reasoning in distinguishing one’s own mental state from another and, in the case of deception, in switching between deception and truth during communicative exchanges.

The above neuroimaging example suggests that deceivers may actively reason about others’ mental states. Although plausible, more evidence is still needed given the relative lack of research

in this area. An alternative explanation is that deceivers may be drawing from an implicit theory of mind that is more cognitively efficient, requiring only simple belief attributions about another. Such an account is better suited to the demands of actual communication in which people rapidly and seamlessly exchange information in a coordinated fashion. Extensive reasoning about what another understands during communication is seen by many as being incompatible with the real-time dynamics of social interaction. Furthermore, the cognitive demands of explicit mental state reasoning, coupled with the demands of having to overcome a truth bias, might also disrupt deceivers’ linguistic and nonverbal behaviors to a point where deception is easily detectable. Existing

*David Oppenheim is deep in concentration at the 2010 World Series of Poker in Las Vegas, Nevada, June 1, 2010. The ability to consider and make inferences about the mental states of others, invaluable to lie detection experts, deceivers, and poker players alike is commonly referred to as “theory of mind.”*

research suggests otherwise, with detection rates in interpersonal interaction often being no better than chance. Thus, given the frequency and ease in which people lie, the possibility of a more implicit theory of mind is likely warranted.

been suggested to function as a lie detection tool. A liar's fear of getting caught is assumed to bring about a surge of blood flow, thereby increasing facial temperatures. Studies found that 69 to 92 percent of liars and 60 to 92 percent of truth-tellers could be correctly classified through thermal imaging technology, indicating thermal imaging has potential as a lie detection device. Many issues remain to be resolved, however, in particular the concern that thermal imaging will erroneously regard the truth-tellers arousal (for example, fear of flying, stress of being interviewed) as a sign of deceit.

Originally, thermal imaging was developed during the Korean War to enhance vision during nighttime and to detect enemy objects. Later on, it gained a wide application in a variety of fields, such as security, firefighting, industry, medicine, and science. Thermal imaging cameras measure the invisible infrared radiation emitted by objects and convert it into colored-pixel images, called thermograms. As the infrared radiation emitted by an object is a function of its surface heat (that is, the higher an object's temperature, the greater the intensity of radiation it emits), the color gradients of the image reflect variations in temperature. Thermal imaging makes it possible to see one's environment better, with or without daylight. Warmer objects, such as humans or animals, thereby easily stand out from typically cooler backgrounds.

### Accuracy as a Lie Detection Tool

In 2002, Ioannis Pavlidis and colleagues proposed thermal imaging as a lie detection tool in a brief communication in *Nature*. Departing from the assumption that liars experience anxiety about being caught, liars are expected to show a fight-or-flight reaction. This reaction is the response of the sympathetic nervous system to a stressful event, preparing the body to fight or flee, and is characterized by an increased blood flow to the brain and muscles. The increase in blood flow leads to a heightened body temperature, which can be picked up by a thermal imaging camera. Prior research indeed showed that a startle response elicited by an auditory noise is accompanied by heating of body temperature, particularly around the eyes. By focusing on thermal patterns around the eyes, Pavlidis and colleagues could correctly classify 75

## Thermal Imaging

Thermal imaging is the technique that depicts the temperature variations of the environment using thermal imaging cameras. Thermal imaging has

percent of the liars and 90 percent of the truth-tellers in a mock crime study, when participants replied to the question “Have you stolen \$20?”

The authors claimed that the thermal imaging technique has an accuracy comparable to that of the polygraph. Moreover, because thermal imaging can occur rapidly, without the need for skilled staff or physical contact, they argued that it could be used for instantaneous lie detection without the subject being aware. One apparent application they suggest would be mass airport screening, in which the thermal pattern of every passenger’s face could be measured nonintrusively, thereby instantly identifying the wrongdoers among them. In an erratum, the authors later toned down their claims, stating it was premature to propose thermal imaging for large-scale truth screening.

The study did not go unnoticed and caused considerable controversy; the fact that no control questions were used threw a shadow on the boldness of the authors’ claims. Participants only responded to one question that explicitly referred to the mock crime. Such a question may also be anxiety-provoking for innocents, thereby increasing the risk of falsely accusing innocents (also known as the Othello error). A comparison with questions that control for the effect of the generally threatening nature of relevant questions is therefore an absolute must.

Screening subjects without their awareness circumvents the problem that innocents may become nervous in the interrogation situation, but it does not control for individual differences. People have different baseline levels of anxiety, differ in their susceptibility to stress, and may experience anxiety for many reasons other than deception. In airports, for example, innocent subjects may display nervousness because they have a fear of flying or worry about missing their plane. Later research indeed showed that thermal imaging could not discriminate truth-tellers and liars prior to being interviewed. An interview protocol is thus essential to reliably apply thermal imaging in a deception context.

Until now, a handful of studies have implemented thermal imaging during three interview protocols. Some studies used the control question technique, in which a crucial question (for example, “Did you remove the check from the envelope?”) was compared to other anxiety-provoking

questions related to the crime (for example, “Is everything you have told me about the check the truth?”). One study designed neutral questions that should only evoke concern in liars. Passengers at the airport were asked unexpected questions about their forthcoming trip (for example, “Have you been there before?”). When asked unanticipated questions, liars have to fabricate their answers on the spot, which is mentally taxing. As a result, they may struggle with their answers and become afraid of not being believed.

Finally, some studies applied the concealed information test, in which deceptive subjects were asked to hide recognition of known relevant items (that is, items related to a mock crime) embedded in a series of irrelevant items. The studies showed that 69 to 92 percent of liars and 60 to 92 percent of truth-tellers could be correctly classified based on thermal imaging data.

In a nutshell, laboratory studies have shown that thermal imaging can discriminate between liars and truth-tellers above chance level, which makes it a potential lie detection device. The technique cannot be reliably applied in a one-question format or outside an interview context, as suggested by pioneers. When used in interview protocols, thermal imaging can classify liars and truth-tellers with 60 to 92 percent accuracy. One should bear in mind, however, that the studies used different methods and analyses that capitalized on chance. Cross-validating each specific method and analysis in an independent sample is therefore necessary to establish firm conclusions.

Moreover, researchers should acknowledge that interview protocols differ in their sensitivity to the Othello error. Accumulating evidence from polygraph research has shown that the control question technique leads to a troublesome number of misclassified innocents because of its flawed rationale: Guilty suspects will not necessarily show stronger responses to crucial questions, whereas innocent suspects may respond strongly, for example, because they fear not being believed. Even neutral questions that should only evoke concern in liars may in real life also elicit arousal in innocents when they realize the consequences of failing to convince the interviewer.

The only protocol that contains safeguards against the Othello error is the concealed information test. Only guilty suspects should recognize

the relevant items and become concerned of not being able to hide this. Thermal imaging may therefore serve as an interesting covert measure in polygraph examinations that use the Concealed Information Test.

(challengers) who all claim to be the same person. The host reads a signed affidavit from the real person, and the panelists then ask the challengers questions. One challenger is sworn to tell the truth, and the other two are imposters who lie and attempt to deceive the celebrities into thinking they are the real person. The imposters are not only encouraged to lie, they receive cash prizes for effectively deceiving the panel. Each panelist then guesses who is telling the truth. In two versions of the show, the studio audience also votes. The truth-teller then reveals himself after the host asks, "Will the real [person's name] please stand up?" The challengers receive prize money based upon the number of wrong guesses, incentivizing their ability to bluff effectively.

The truth-tellers came from fields including the arts (Hunter S. Thompson, Berry Gordy Jr., Stan Lee), business (Orville Redenbacher, Mary Kay Ash), and sports (Tony La Russa). Some of the imposters also became famous later in life, such as Anderson Cooper, who appeared as an imposter when he was a child.

#### Broadcast History

*To Tell the Truth* debuted on December 18, 1956, on CBS during prime time as *Nothing But The Truth*. The show was quickly renamed and remained on CBS until 1968. Mike Wallace (who later appeared on the television program *60 Minutes*) hosted only the pilot episode; Bud Collyer (the voice of Superman on the serialized radio drama *The Adventures of Superman*) served as the show's first host. The show also featured a variety of narrators across the six decades.

*To Tell the Truth* added a daytime five-day-per-week version in June 1962, which featured a different panel of celebrities (though the same host and narrator as the prime time version), less prize money, and only presented two games instead of three to allow time for a news break. In 1965, the prime time panelists replaced the daytime panelists and, toward the end of the daytime show's run, the studio audience voted as well as the panelists. The prime time show ended in 1967; the daytime version lasted until 1968.

The show's first syndicated run lasted from 1969 to 1978. Interestingly, this version debuted the same day original host Collyer died. Replacement host Garry Moore left the show in 1976

---

## To Tell the Truth

*To Tell the Truth* was one of the most successful American television shows of all time, with new episodes in each of the six decades between its 1956 debut and the cancellation of its most recent version in 2002. In the past 50 years, *To Tell the Truth* has offered American audiences an innovative game of deception, showcasing how difficult it can be to determine who is telling the truth and how easy it is to deceive others.

#### Playing the Game

At the beginning of the game, a panel of four blindfolded celebrities meets three individuals

after being diagnosed with throat cancer. A second syndicated version started in 1980. It lasted only one year, despite the addition of a new game called “One-On-One,” in which the celebrity panelists were given a fact about one of the four imposters and asked which former imposter was telling the truth.

The show’s least successful version aired on NBC for nine months, starting in 1990. It went through three hosts, including Alex Trebek, who was hosting *Classic Concentration* and *Jeopardy!* at the same time, making Trebek the most omnipresent TV game show host in American history.

In 2000, the show returned to syndication for two seasons. John O’Hurley hosted. This version brought back the audience vote that had only appeared in the CBS daytime version. Kitty Carlisle appeared as a celebrity panelist in one episode, making her the only person to appear on every version of the show across the six decades. If a new version of *To Tell the Truth* debuts before 2020, it will regain a tie with *The Price Is Right*, also created by Bob Stewart, which has aired new episodes across seven decades.

### Popular Culture

A show that has spanned six decades is certain to etch itself into mainstream popular culture. One of the most memorable instances of this appears early in the Oscar-nominated movie *Catch Me If You Can*. In the film, Leonardo DiCaprio portrayed Frank Abagnale Jr., a con man whose autobiography inspired the Steven Spielberg-directed film. The film places DiCaprio, as Abagnale, into the original footage of when Abagnale was the challenger on a 1977 episode of *To Tell the Truth*. In the episode, Abagnale is in the center, dressed as a pilot, while the imposters are dressed as a doctor and a prisoner. None of the four celebrities correctly identified Abagnale.

### Research Application

Throughout its many versions, *To Tell the Truth* offers support to empirical evidence that people are not effective at detecting deception. Further research could examine the thousands of episodes of *To Tell the Truth* to validate whether the imposters match empirical research demonstrating that deceivers tell less compelling stories, shy away from unordinary events, and are less likely

to provide direct eye contact with their questioners. While some research finds that deception cues are more obvious when the imposter is motivated to succeed, the great success of many imposters across six decades of *To Tell the Truth* might limit these findings in the TV game show context.

## Tobacco Advertising

Over the last 60 years, major tobacco companies have responded to each new study, finding, and law regarding the dangers of tobacco by producing misleading advertising claims. Competition among tobacco companies drove the initial use of deception in advertisements. With the release of public information on the connection between tobacco use and lung cancer, however, companies’

### The Doctors behind the Doctor

● Magical penicillin... the amazing "sulfa"... and now the new streptomycin... Think the men of research medicine for these... and for all the other valuable aids they have placed in the doctor's "first aid kit."

● Biochemists and bacteriologists... pathologists and physiologists... whatever the field of research... they are first and foremost, doctors! And, like all doctors, they are tirelessly devoting their lives to the cause of human health and happiness.

*According to a recent Nationwide survey:*

## MORE DOCTORS SMOKE CAMELS THAN ANY OTHER CIGARETTE

● What cigarette do you smoke, Doctor?... that was the question put to 113,597 doctors from the Atlantic to the Pacific, from the Gulf of Mexico to the Canadian border. Three independent research organizations did the asking... covered doctors in every branch of medicine.

*The brand named most was Camels!*

Like the rest of us, doctors smoke for pleasure. Their taste recognizes and appreciates the rich, full flavor and cool mildness of Camels' choice tobacco just as yours does.

OUR "T-ZONE" WILL TELL YOU...

T for Taste...  
T for Throat...  
that's your proving ground for any cigarette. See if Camels don't suit your "T-Zone" to a "T."

**CAMELS** Costlier Tobaccos

*This 1946 Camels cigarette magazine advertisement was typical of tactics that invoked science to make false claims about the health benefits of tobacco, designed to ease public concerns about the adverse effects of smoking.*

false advertising shifted toward counteracting negative publicity and stressing the benefits of tobacco products. Bans on the terminology, imagery, and spokespeople resulted from these false health advertisements.

Companies were forced to change their sales strategy to the development of new tobacco products rather than prove the health benefits of regular cigarettes through advertising. Although these new products were equally harmful to consumers, advertisements touting features such as "filtered," "light," "mild," and "natural" suggested the products to be healthier alternatives than regular cigarettes. In addition to creating new types of tobacco and cigarettes, companies released advertisements emphasizing cigarettes as a way to reduce stress and anxiety. New laws and regulations in response to each change in advertising strategy restricted the tobacco industry, driving

companies to more discreet and subliminal advertising to maintain brand presence.

### The Start of a Century-Long Campaign

Deceptive tobacco advertising first originated from competition within the tobacco industry. Different brands attempted to obtain market share through exaggerated and false claims about tobacco products. The introduction of menthol cigarettes in the mid-1920s led to deceptive advertisements about the refreshing, clean, and soothing feeling smokers would receive from menthol cigarettes, regardless of how much they smoked. These advertisements also claimed that menthol cigarettes were healthier than regular cigarettes, despite findings that menthol cigarettes could actually encourage consumers to smoke even more.

The false claims for menthol cigarettes began a century-long campaign to convince consumers of tobacco's healthiness. Morton Levin, the director of Cancer Control in the New York State Department of Health, published the first major study linking smoking to lung cancer in 1950. To combat such bad publicity, tobacco companies joined forces, creating the Tobacco Industry Research Committee to investigate the health issues surrounding tobacco. "A Frank Statement to Cigarette Smokers," was an advertisement featured in 448 newspapers across the United States. It announced the creation of the research committee and claimed that cigarettes were not harmful to smokers' health. The tobacco industry created the research committee and subsequent advertisements as parts of a public relations strategy to spin research findings as controversial rather than definitive. The committee was funded by the tobacco industry to conduct research projects that could deceptively reduce the impact of studies against tobacco.

Following the release of the new research findings, an advertising battle among tobacco companies ensued as different brands competed to appear as the healthiest option to consumers. Advertisements made false claims, including that specific brands could calm nerves and lead to happier and healthier lifestyles. These health appeals even included advertisements for Camel cigarettes that stated, "More Doctors Smoke Camels than any other cigarette." The Federal Trade Commission

(FTC) consequently banned advertisements featuring health references and words such as doctor, nerves, and energy. The new ban forced tobacco companies to reevaluate their marketing strategies and move toward creating new products that could be marketed as healthier without violating the FTC bans.

### **Filtered, Low-Tar, and Natural Cigarettes**

The first of these new products was the filtered cigarette, which companies advertised as lessening the amount of smoke users inhaled. Filtered cigarettes quickly took over the market in the late 1950s as smokers searched for alternatives to quitting. Advertisements focused on the positive-sounding traits of the filtered cigarettes and omitted the fact that they were just as harmful as regular cigarettes because of the stronger tobacco used. These advertisements stressed the purity and neatness of smoking filtered tip cigarettes over regular cigarettes. As a result, companies were able to bypass the FTC bans, yet still contradict health claims.

Tobacco companies continued to employ an advertising strategy focused on new product development and the manipulation of language to sidestep bans. Following filtered cigarettes, companies created “low-tar” cigarettes. These cigarettes were again advertised as healthier, though in reality they had the same dangerous health effects. Industry papers released to the public showed that tobacco companies knew of the dangers, yet intentionally deceived consumers. To insinuate the healthiness of “low-tar” cigarettes without violating the FTC bans against health terms, companies labeled cigarettes as “light” and “mild.” Some advertisements even suggested that smoking “light” and “mild” cigarettes was better than quitting smoking.

“Low-tar” cigarettes became the best-selling tobacco product, causing the advertising battle among companies, referred to as the “tar derby,” to continue. Each brand fought to advertise its cigarettes as having the least amount of tar. In 1960, the FTC told tobacco companies to end the tar derby and refrain from suggesting the improved health effects of filtered cigarettes.

However, this event was followed by the Surgeon General's first report on the link between tobacco and lung cancer in 1964. Companies

continued the tar derby in attempts to counter the report's findings. The development of new products continued throughout the 1970s and 1980s, as different companies produced cigarettes with even lower tar and nicotine. In the late 1990s, companies again tried to differentiate from competitors by releasing “natural” cigarettes. While just as dangerous, the terminology used in advertisements such as “unprocessed” and “additive-free” suggested that natural was equivalent to healthier. The FTC eventually forced Winston, one of the primary natural cigarette brands, to include the statement “No additives in our tobacco does not mean a safer cigarette” in its advertisements.

### **Covert Advertising and Health Imagery**

Tobacco companies also battled FTC bans and health research through covert advertising. Popular writers published articles expressing doubt over the tobacco-cancer link in major magazines and newspapers in return for compensation from tobacco companies. In 1968, a public relations company working for a tobacco company paid Stanley Frank, a sports writer, to write an article for *True Magazine* in which Frank said that the link was inaccurate. Frank also wrote a similar article for the *National Enquirer* under a fake name. Tobacco brands then referenced Frank's article and similar news stories in advertisements for products.

Tobacco companies also attempted to sidestep the bans on the language of advertisements by employing health imagery. Many tobacco advertisements featured people smoking while performing adventurous outdoor tasks. These advertisements tried to create a positive association with smoking and were not often seen as deceptive, just psychologically persuasive. However, the FTC found that the advertisements were deceptive, as the characters smoked during intense athletic activity, such as hiking or playing a sport. The activities shown require more than just normal respiratory strength, contradicting the link between tobacco and poor respiratory health. The FTC consequently banned advertisements in which characters smoked during activities that required “stamina or conditioning beyond those required in normal recreation.” Tobacco companies responded, however, by releasing advertisements in which characters smoked just after

finishing a difficult sport or activity, evading the FTC's ruling.

### Current Advertising Practices

Tobacco advertising is now much more limited than in previous years. Tobacco companies cannot advertise on television, radio, or in magazines whose readers are below the age of 21. In most states, smoking is banned in restaurants, bars, government buildings, hospitals, workplaces, and on mass transportation. Antitobacco campaigns work to create an environment in which there is social pressure to quit smoking and the public looks down on the act. As a response to these societal changes and the FTC rulings, tobacco companies have shifted advertising focus to status imagery. Despite the negative social views toward tobacco, companies market cigarettes as symbols of status, wealth, and "coolness." Images of attractive people dressed in expensive clothing and surrounded by friends adorn tobacco advertisements.

With the ban on broadcast advertisements, companies resort to product placement in movies to promote cigarettes as trendy. Such organizations pay millions of dollars to feature popular celebrities smoking while playing high-status characters, indicating that the FTC bans have driven tobacco companies to subliminal advertising to mislead consumers.

The FTC attempts to regulate the tobacco industry's manipulation of fact, especially when this information is unlawful and counteracts anti-tobacco campaigns. Although today's deceptive nonverbal advertising may be considered morally objectionable, the FTC has not yet found it illegal. Despite regulation and the definitive knowledge that tobacco is unhealthy, tobacco companies continue to deceive consumers about the value of cigarettes and other tobacco products in their lives. Tobacco advertising has been replaced by more subtle types of deception, which misleads through symbolism and nonverbal content. Regardless of the way messages are transmitted, companies continue to imply that smoking has some intangible benefit to consumers.

## Torture

Torture is any one of intense interrogation methods used to elicit involuntary information disclosure from another person. These methods have been historically sanctioned by states as justified by the end goals of national security and public safety, though they have also increasingly been challenged on legal, moral, and ethical grounds during the past half century. As such, torture's use is an issue that is globally under debate and in transition. False confessions occur when individuals lie to interrogators to stop the torture. The present discussion focuses solely on the relationship between torture as an interrogative technique and lying as a potential outcome and/or obstacle to be overcome by torture, as distinguished from acts performed for the torturer's pleasure. By most reports, professional interrogators using torture are neither sadistic nor do they perform torture for their pleasure. Many simply view torturous acts as tools of their trade, similar to other interactive methods, differing in intensity.

Historically, some confessions were only legally admissible if elicited under torture because other testimonies were deemed less reliable and valid. Torture continued to be viewed as a legitimate means of law enforcement inquiry through medieval and early modern times in Western cultures. One well-known period of torture use was during the medieval Inquisition, lasting nearly 600 years, and ending in the early 19th century. Torture was

also used ubiquitously during trials to elicit confessions of witchcraft. Often, torture was used to elicit the names of accomplices and conspirators of a suspect.

Napoleon Bonaparte felt that torture, as a method of interrogation, was useless. Torture is currently viewed as a violation of the Geneva Conventions, as well as those United Nations' guidelines articulated and ratified across nearly 150 countries, yet torture is still practiced by approximately 80 countries. However, these United Nations guidelines are not legally binding as part of international law, and many participating states are hesitant to frame their practices as torture, because of resulting negative domestic and international perceptions.

Modern torture techniques are often designed to leave no telltale marks on suspects, diminishing a suspect's credibility when claiming torture, and permitting plausible deniability for states and their interrogators. Psychological torture techniques are sometimes favored when the suspect will be freed; however, while not visible, these techniques' damages can be as severe and long-lasting. Thus, while psychological or physical pain and discomfort is frequently used in interrogations, actual harm can sometimes distinguish torture from other severe interrogation techniques. Though delineation between torture and other more "legitimate" interrogation techniques is not commonly agreed upon, torture usually involves some level of suffering beyond minimal levels, and that suffering can last well beyond the interrogative event. In many legal systems, as long as the pain and suffering inflicted on a prisoner or suspect is not "severe," it is permissible to use physical force to cause "discomfort."

As terrorism increases throughout the world, law enforcement and intelligence communities have increasingly turned to more intensive interrogation techniques to quickly elicit relevant information from suspects in order to prevent destructive acts. The "ticking time bomb" scenario is commonly invoked in defense of interrogative torture. In some cases, these techniques fall into legally grey areas, and in others they may even violate laws. Yet, the United Nations Convention Against Torture expressly reproaches any justification of torture, including states of war or threat of war, political instability, public

emergency, or on order from authorities. This agreement also forbids states from moving suspects to other states where they may be subjected to torture, thereby "outsourcing" torture, or providing "torture by proxy" in which information is elicited by one state, and then routed back to the original state. Both the Red Cross and Amnesty International help monitor situations to prevent the use of torture.

### **Is Torture an Effective Interrogation Technique?**

Torture is inherently a communicative activity, designed to elicit useful information from an individual who does not wish to disclose it. Though studies have shown that torture tactics are meant to lead to positive results, they can involve harsh physical, verbal, and psychological techniques, compelling suspects to even falsely confess. While police and other officials use methods that might seem negative, cruel, or unpleasant to some people, the use of these tactics is viewed as necessary at times, and can protect innocent civilians by helping close cases and identify dangerous individuals. However, many terrorists are trained in methods of resisting police and military interrogation, therefore reducing the effectiveness of these methods.

In the United States, skilled interrogators have concluded that these harsh techniques are less effective than psychologically oriented techniques in obtaining truthful statements from terrorists. Robert Mueller, director of the Federal Bureau of Investigation, dismissed the effectiveness of such torture techniques as waterboarding, challenging reports that information from such techniques disrupted any domestic attacks. Although delayed from being released to the public, a report by the inspector general of the Central Intelligence Agency (CIA) similarly called into question the effectiveness of "enhanced interrogation" techniques used by CIA interrogators. Further, after coercive practices were banned in Iraq, military interrogators saw dramatic increases in "high-value" intelligence.

As such, torture may be an ineffective coercive technique. Once damage or severe suffering occurs, the threat of inflicting damage or suffering to the individual is removed, and it is this psychological pressure that makes other interrogation

techniques more effective. Once harm occurs, individuals may say anything to the interrogator to stop the torture, including lying.

### Is Torture Legal?

Reports on the misuse of interrogation of terrorists raise the question of whether limits on interrogation should be more strictly enforced. In the United States, the constitutional limits on police interrogators depend on the purpose of the interrogation. If there is an immediate concern for protecting the public, such as against terrorist actions, the U.S. Supreme Court has held that agents may question the suspected terrorists without first warning them of their Miranda rights. The Miranda rights, mandated in the 1966 U.S. Supreme Court decision in *Miranda v. Arizona*,

state that suspects can decide at any time to exercise their rights and not answer any questions or make any statements. Further, the Fifth, Sixth, and portions of the Fourteenth Amendments to the U.S. Constitution protect the rights of people against false confessions, and of producing either an involuntary or untrustworthy confession, resulting from coercive tactics. The Fifth Amendment determines if a confession is to be considered valid based on its level of voluntariness.

Persuasion is based in the idea of gaining compliance. The main focus of interrogation is to facilitate and increase the suspect's compliance and subsequent self-disclosure. The vast majority of interrogation techniques are designed to elicit a confession voluntarily, whereas the use of torture elicits confessions involuntarily. Coercion can be used as an interrogative tactic to obtain confessions with two types of problematic coerced confessions: (1) coerced-compliant false confessions, when the suspect confesses in order to obtain a goal, or to relieve him or herself of a difficult position or situation; and (2) coerced-internalized false confessions, when a suspect becomes uncertain of her or his innocence after becoming confused and begins to doubt themselves because of manipulative and coercive interrogation tactics adjusting their perceptions of reality. Thus, for a confession to be considered valid, it must be voluntarily offered, without coercive pressure.

### Is the Information Valid?

There are numerous persuasive techniques that can be used in interrogation. Additionally, several coercive interrogation techniques may be used, with the most severe of these being considered torturous. The age, compliancy, susceptibility, and mental development of the suspect can greatly impact an interrogation. The tactics used in interrogation settings can affect the suggestibility of suspects, as well as their anxiety levels. While this can cause the suspect to provide the investigator with the sought-after information, it can also lead to false confessions.

Interrogators themselves are often in stressful situations in which the time to elicit information from a suspect is minimal, and negative impacts of not getting the desired information are not insignificant (for example, death and destruction).

Antonio Tempesta's woodcut depicts the torture and execution of Christians in Antonio Gallonio's *Tortures and Torments of the Christian Martyrs*, first published in 1591. Torture has been used throughout the centuries in an attempt to elicit false confessions from individuals, including false confession of a religious belief.

Thus, an “ends justify the means” mentality can emerge or prevail. Interrogations, which seek to determine the culpability of a suspect with regard to a crime, often result in false confessions. A false confession is when a suspect admits to being guilty of a crime that she or he is innocent of committing. Suspects often confess despite the fact they are innocent, in the hope of gaining notoriety or shelter, or controversially because they are pressured by interrogators.

Though detection of lies and false confessions can be aided by technology (e.g., polygraphs, functional magnetic resonance imaging), given the lack of deception detection accuracy shown by meta-analyses of lying and deception, measures should be taken to ascertain the validity of the information being given, if not to avoid situations in which false content/confessions might be elicited from individuals. It is difficult to consciously control all behavioral channels, and nonverbal communication “leaks out” through facial, vocal, and/or bodily expressions, providing interrogators with clues that a suspect may be withholding or providing false information. By analyzing eye movements, spoken predicates, and posturing, it is thought that interrogators can determine the validity of suspect statements. Even the use of time can lead to confusion and to a lessened sense of reality. By interrogating at night, interrupting sleep patterns and eliminating time for sleep, it is hoped that a truthful confession will be obtained from an overtired, stressed, guilty suspect.

Along with sleep deprivation, there are many other aspects of the interrogation process that cause stress and increase anxiety in the suspect. A suspect’s arousal level (that is, ability to withstand additional stimulation) can affect how anxious she or he is while being interrogated. A person with a high arousal level would become overstimulated during an interrogation and, therefore, may confess more easily in order to end an interrogation and return to a comfortable level of arousal. A person with a low arousal level (that is, a stimulation seeker) would be better able to withstand a lengthy interrogation, and more intensive interrogation techniques would have to be used in order to reach an arousal level causing her or him to confess. If the interrogator yells or varies her or his vocal patterns, the person being interrogated

becomes more stimulated, potentially leading to higher anxiety.

Juveniles, compliant personalities, and mentally handicapped people are the most prone to falsely confess to a crime; yet, without observable signs, identifying most mentally handicapped individuals prior to or during interrogations may be difficult. There are numerous measures that can be taken in order to prevent false confessions. The length of the interrogation can be limited. Some courts have allowed interrogations longer than five hours; however, lengthy interrogations signify to the suspect that the only way to end the interrogation is to give in and confess. Trickery is also likely to produce a false confession, such as deceiving a suspect in regard to the evidence that is held against her or him.

Another effective measure in preventing false confessions is videotaping or recording interrogations. Approximately one-third of all law enforcement agencies in the United States already take this measure, and it is required for police interrogations in England to be videotaped. Videotaping does not jeopardize legitimate law enforcement agencies, and when interrogations are fair, it produces powerful evidence for prosecution.

Many tortured individuals can experience signs of post-traumatic stress disorder (PTSD); this experience may be further amplified if the individual divulged information leading to the torture or deaths of others, resulting in feelings of deep guilt. Some courts recently have concluded that while information gleaned under torture conditions might not be admissible in court, law enforcement agencies could still act upon the information to help ensure public safety (for example, time bombs).

## Conclusion

The persuasive methods used in the interrogation process are meant to help elicit valuable information, rather than harm suspects. Interrogators use powerful techniques to gather information from suspects. Use of harsh interrogation techniques creating severe distress in a suspect can constitute torture, often rendering information divulged during interrogation unreliable, and producing lasting harm in the mental and/or physical state of the suspect, making the process a problematic endeavor on multiple levels. A recurring theme

in research pertains to false confessions resulting from harsh interrogation. A problematic situation occurs when an individual confesses, but is not guilty, thereby derailing or even halting investigations of crimes or intelligence missions, and damaging an innocent individual. While torture has clearly been shown to be an effective technique in extracting confessions when the suspect is guilty, even more effective interrogation techniques seem to avoid the problematic aspects of torture.

## Transparent Liars

Transparency in general refers to the openness of liars in telling lies and the openness of truth-tellers in telling the truth. Transparent liars are disbelieved when they are lying, whereas nontransparent liars are believed when they are lying.

In the psychological literature on lying, transparency was identified with how leaky liars were when lying. Traditionally it was held that leakage was prevalent among liars, especially in the case of lies that were not sanctioned and when there was something important at stake for the liar (high-stakes lies). That is, traditionally it was held that most liars were transparent. Recent research on lie detection has cast doubt on this claim about the prevalence of leakage and has argued instead that leakage among liars is much more variable: leakage is the exception rather than the rule for liars. The conclusion is that there are far fewer transparent liars, and many more nontransparent liars, than studies originally held.

In the work of Paul Ekman and Wallace V. Friesen in the late 1960s and 1970s it was determined that liars typically experience certain emotions, such as guilt (about telling lies) and fear (being detected when they tell lies). It was also determined that liars can experience delight in succeeding in duping people. Truth-tellers, by contrast, do not typically experience these emotions in telling the truth. Although liars may attempt to suppress these emotions and control the display of these emotions, by attempting to hide the emotions with a mask of neutrality (maintaining a "poker face"), or covering the truly felt emotion with a different, false emotion,

emotions are not normally under the conscious control of liars. In addition to verbal cues that signal lying, such emotions can be leaked to the recipients of lies, nonverbally, and hence are also cues that signal lying.

This idea of leakage was expanded upon by researchers in the 1980s such as Miron Zuckerman, Bella M. DePaulo, and Robert Rosenthal, who advanced a four-factor internal state theory. Liars, as opposed to truth-tellers, are more likely to experience greater levels of arousal, emotions (such as guilt and fear), greater cognitive effort, and more effort to control their nonverbal displays of emotion. Each of these internal states was thought to be associated with certain nonverbal behaviors; for example, in the case of increased cognitive effort, lying was thought to lead to an increased number of speech errors and longer response latencies. Even if liars presented themselves as honest, therefore, they leak cues to their own lying, both verbally and nonverbally.

If liars typically leak cues to their own lying, then it follows that liars are typically transparent liars. Because this conclusion was at odds with lie detection experiments, in which subjects are, on average, only 54 percent accurate in detecting liars, or only slightly better than chance, researchers argued that people are poor at detecting leakage, at least without training. As it were, people are poor at detecting transparent liars.

More recently, researchers such as Bella M. DePaulo and Charles F. Bond have determined that there is much more variance in liars' transparency and much less variance in people's ability to detect lies, even if variance in transparency is not large in an absolute sense. The majority of people can lie without leaking, or without leaking very much, to the recipients of the lies they are telling. That is, the majority of people are not very transparent liars. A small proportion of people, however, have a tendency to give themselves away and to leak that they are lying. That is, a small proportion of people are transparent liars. Although not perfectly transparent, such transparent liars are detected by the recipients of their lies.

In traditional experiments with lie detection, which were set up so that subjects must rate people they view in videos as lying or not lying, subjects were not able to ask questions of the putative liar.

Also in such experiments, various kinds of information were excluded, such as whether or not the people had a reason to lie (in the experiments, it is normally the case that no reason is apparent, or that all people have the same reason). In addition, prior factual knowledge was excluded and access to physical evidence was precluded, along with information about the context, knowledge of confessions, and other data. In such artificial experiment conditions, there can be no strategic use of evidence, and no strategic questioning, among other things. The result is that the subjects in such lie detection experiments had to almost exclusively rely upon liars being transparent in order to detect them.

### **Few Transparent Liars Model**

It has been argued by researchers such as Timothy R. Levine that, as a consequence, the results of such lie detection experiments tell more about the transparency, and lack of transparency, of the liars than about people's general ability to detect lies. The results of such experiments, it is argued, are a function of the relatively small number of transparent liars and the large number of nontransparent liars. This has led to the Few Transparent Liars Model in order to explain the surprisingly poor results in such experiments with lie detection. It is not that people are, in general, poor at detecting lies. Rather, they are poor at detecting lies under such conditions, when relying almost entirely upon transparency, because there are few transparent liars and many nontransparent liars.

This raises the question of why so few liars are transparent liars. The most plausible explanation is that people become less transparent in lying through practice at lying. Although children's lies are highly transparent and, as a result, are discouraged and/or punished by adults, children gradually learn to avoid detection through trial and error and become less transparent over the years. By early adulthood, most people are nontransparent liars.

This explanation raises the further question of why, nevertheless, some people remain transparent liars. Various explanations have been offered for this. One explanation is that some people are simply more practiced at lying than others and become more nontransparent in lying. Those with

less practice at lying remain transparent liars. A second explanation is that there are differences in natural ability among people, such that some people benefit from practice at lying more than others. Those who lack the natural ability remain transparent liars, despite practice and, as a result, are discouraged from continuing to attempt to lie.

Finally, it is thought that transparency in lying can vary as a result of situational and chance factors and that transparency in lying should not be thought of as an invariable trait. Although some people may be transparent in almost all situations, others may exhibit transparency in one situation rather than another. Furthermore, even nontransparent liars could become more transparent as a result of strategic questioning.

The conclusion that most people are not transparent liars—that most people are relatively good at lying—does not necessarily run afoul of evolutionary theory. It may well be that human susceptibility to being duped by lies reflects a highly adaptive trade-off. A cognitive system that evaluated all information for veracity would be less efficient than one that presumed truthfulness and subsequently rejected what was discovered to be false. If this system is further combined with social systems that discourage lying, then it will be even more efficient. Such an explanation would predict that parents will teach their children that lying is wrong and that all human cultures will develop prohibitions against lying, at least within the in-group. All human cultures benefit if lying is condemned and if people are made to feel shame upon being discovered to be a liar.

## Trojan Horse

The Trojan Horse comes from the story of how the Greeks, by guile and deceit, won the Trojan War. The original Trojan Horse was a large wooden contraption in which a small group of Greeks hid in order to secretly enter Troy and thereby initiate its demise. The term *Trojan Horse* has subsequently come to be used for several different forms of deception.

The legendary Trojan Horse was a contrivance that allowed the ancient Greeks to finally end the 10-year siege of the city of Troy and conclude the Trojan War. In the 13th century B.C.E. a coalition of Greek city-states was formed to wage war on the powerful city of Troy in Asia Minor. The primary literary sources for the Trojan War are several ancient works of Greek and Roman literature, principally the *Iliad* of Homer, as well as Book IV of Homer's *Odyssey* and Book II of Virgil's *Aeneid*, which describes the sacking of Troy.

The Trojan Horse was a ruse to help the Greeks finally conquer Troy. The horse was actually regarded as a sacred animal by the Trojans. The wood used to make the horse was cut from trees in a grove sacred to the god Apollo. The crafty Greek hero Odysseus took credit for the idea of the ploy, said to have been given to him by the goddess Athena in a dream. The Trojan

Horse consisted of a large wooden figure of a horse built in just three days under the direction of Epeius, a talented boxer, with the guidance of Athena. The Trojan Horse was constructed with a hollow belly, in which Odysseus and a small contingent of elite soldiers could conceal themselves. An inscription was written on the side of the Trojan Horse that said the horse was an offering of gratitude to Athena for pleading for the safe return of the Greeks on their long journey home.

The Greek army broke camp and boarded its ships as if to return home to Greece. However, the fleet hid behind the island of Tenedos, off the Trojan coast. The Trojans then entered the remnants of the Greek encampment and saw the colossal Trojan Horse. They also found a lone Greek, Sinon, who had been coached by the wily Odysseus as what to say to the Trojans. Sinon told the Trojans he had deserted from the Greeks, whom he said wanted to sacrifice him, and he said the Trojan Horse was left as a peace offering to the gods. Sinon added that the Greeks had made the horse very large so that the Trojans could not bring it into their city. He also said that the Greeks hoped that the Trojans would desecrate

the Trojan Horse and thereby incur the divine wrath of Athena.

Most of the Trojans thought the Trojan Horse would make a great trophy and wanted to bring it into their city. However, at least two of the Trojans warned against accepting the Trojan Horse. One of these was Cassandra, the daughter of King Priam and Queen Hecuba of Troy; she had been given the gift of prophecy by Apollo, but he also cursed her, when she resisted his amorous advances, such that no one would believe her prophecies. She walked around and around the Trojan Horse, taunting the Greeks inside with insults, including remarks about them and their wives, but the Greeks, at the physical forcing of Odysseus, kept their silence.

The other Trojan who warned against accepting the Trojan Horse was Laocoon, a priest of Poseidon, who said the Trojans should not believe the Greeks, even if they were bearing gifts. Laocoon threw a spear at the Trojan Horse, but then two huge sea snakes were sent by the gods to silence him; the serpents strangled and killed him and his two sons. The Trojans interpreted this as an omen that the gods took displeasure with Laocoon and his warnings. Thus, they continued their plans to

*A small aryballos (vase), from the Corinthian style around 560 B.C.E., displays the story of the Trojan Horse. The legend, which has become nearly synonymous with deception and cunning, was a ruse to help the Greeks finally conquer Troy. A giant wooden horse was quickly constructed with a hollow belly for soldiers to hide in and inscribed with a plea to the goddess Athena for the Greeks' safe journey home. It was left behind as tempting spoils for the Trojans to haul into their city after the Greeks supposedly fled.*

drag the huge statue into their impregnable city, even dismantling some of the city wall as the horse was too big to fit inside the city gates.

The Trojans celebrated heartily, and after many of them became heavily intoxicated, they all fell asleep. That night Sinon went to the Trojan Horse and let Odysseus and his troops out. The troops opened the gates to the city; the rest of the Greek force had returned from their ships and entered the city, sacking and destroying it by fire. The Trojan men were slaughtered, while some of the women and children were taken captive as booty or were sold into slavery.

The sack of Troy by the Greeks was merciless. Temples were desecrated, which garnered additional wrath from the gods of Mount Olympus. King Priam had sought refuge at the altar of Zeus, but Neoptolemus slaughtered him there. Astyanax, Hector's infant son, as well as Priam's grandson and potential heir, was thrown from the city walls. Hecuba, the wife of Priam, was given as part of the spoils to Odysseus, and Andromache, Hector's wife, was given to Neoptolemus. Cassandra, Priam's daughter, was raped by Ajax the Lesser while she was holding on to the altar of Athena; she was later given to Agamemnon. The Trojan Horse had wrought the total destruction of Troy. Nevertheless, some of the Trojans managed to escape, and a few led by Aeneas made their way to Italy, where their descendants later founded the Roman Empire.

### Contemporary Meanings of "Trojan Horse"

"Trojan Horse" is now a term that has several different meanings with respect to lying and deception. In business parlance, a "Trojan Horse" is a deal that appears to be good but in fact is not. It typically consists of an advertised offer, usually of an amount of cash or something else of value, enticing someone to enter into a continuing relationship, such as opening a bank account, cell phone service, or membership in a book club or coffee service; the potential customers are only later informed, typically in fine print, that by accepting the offer, they will automatically be charged service fees in the future.

The term *Trojan Horse* is also used to refer to a computer program that appears to be a legitimate file, but is actually designed to be harmful. The computing Trojan Horse is a nonreplicating

malware program, designed to steal data or to destroy hardware or software, which looks like a harmless application. There are different types of these computer Trojan Horses depending on how they breach the system and the kind of damage they inflict; these include data sending Trojans, denial-of-service attack Trojans, destructive Trojans, FTP Trojans, proxy Trojans, remote access Trojans, and security software disabler Trojans.

## Truth

Truth, in its most general definition, is accordance with reality. That which reflects what is really going on in the world is true; that which does not is false. Truth is the assumed default value of human experience; most people have a general feeling that the information they gain from their senses is what is true. They presume to experience reality and, thus, truth directly. This presumption is largely adaptive. People would not be able to function if they constantly doubted the validity and truth of their experience. Continuous truth judgments about everything one perceives and thinks would cripple one's cognitive capacity and ability to function in society. At the level of individual perception and experience, then, access to truth often is presumed.

Many fundamental institutions in society are structured around the concept of truth. Educational institutions seek to teach it and assume that those who perform well do so without falsehood. Legal systems are designed to discover the truth about crimes and to punish those who deliberately tell lies. Science seeks to discover fundamental truths about the universe, use this information to unravel more truth, and apply these truths practically through technology, medicine, and policy.

Thus, adaptive personal and societal functioning requires knowledge of the truth. But what is truth? This is a far more involved question than it may first seem. The nature of truth has long been a topic of study and debate. Philosophers debate its nature, theologians debate its source, and scientists seek to demonstrate it through study and experimentation. This long history of debate and discovery has led to dozens of theories of truth, each with its own definition of what can be considered truth and what makes it so.

### Philosophical Perspectives on Truth: Inflationary Theories

Inflationary theories are those that state that truth is an actual or substantive property that a statement or proposition possesses. For example, a statement that “the snow is white” can be true or false. Truth (or falsehood) is a property of that statement. Unlike deflationary and epistemic theories, inflationary theories focus on the very nature of truth itself. The three major inflationary theories are correspondence theory, coherence theory, and pragmatist theory.

Correspondence theory states that a proposition is true if it is in correspondence with reality. An assertion that “the snow is white” is only true if it corresponds to the reality that snow is in fact white. The basic form of this theory can be traced as far back as the definitions of truth proposed by Aristotle in *Metaphysics* and Plato in *Sophist*. This theoretical definition has been criticized because it requires a concrete and comprehensive understanding of reality in which to check for correspondence, a so-called god’s-eye view. Nevertheless, correspondence theory is the oldest and most generally accepted of the theories of truth, serving essentially as a default definition of truth for most people. The logic underlying correspondence

theory is very similar to the logic guiding modern scientific theory and its pursuit of truth.

Correspondence theory typically involves a distinction between truth-bearers and truth-makers. While the particulars of these two constructs may vary across different incarnations of correspondence theory, there is a general consensus as to their meaning and use. Truth-bearer is a title given to any entity that may have a truth value, either true or false. Possible truth-bearers include sentences, ideas, and propositions. Truth-maker is a title given to any entity that makes a truth-bearer true. Possible truth-makers include facts, events, and states of affairs that correspond with the truth-bearer. For example, the statement “snow is white” is a truth-bearer, the fact that snow is actually white is the truth-maker.

Coherence theory states that truth is a value placed on an entire system of facts and propositions. Individual facts and propositions are given a truth value only to the degree to which they fit into a broader system. That is, truth only exists within a system, not at the level of individual statements or propositions. The statement “the snow is white” is only true if it fits in with (is coherent with) all other facts that are known about color perception and cold weather precipitation.

This approach to defining truth has been criticized, most notably by Bertrand Russell, because both a given statement and its contradiction can be part of two different coherent systems, thus making both true. For example, contradicting beliefs held by different politicians will cohere to their parties’ systems of belief, but because they are contradictory with one another they both cannot be true. Another common criticism is that unproven and sometimes nonsense statements can cohere perfectly within a system, thus making them true without any evidence. For example, a person could state that there is an undetectable alien race that spies on humanity without affecting the Earth in any perceivable way. By its very premise this statement cannot be proven, yet it can be structured into a coherent set of statements and premises with no conflict among them, making the statement true according to coherence theory.

Coherence theory in some form has existed for hundreds of years. Baruch Spinoza, Immanuel Kant, and Georg Hegel were all adherents to

some form of coherence theory. A resurgence of the theory occurred among early-20th-century philosophers, especially within the British Idealist school.

Pragmatist theory states that something is true if it does not conflict with past experiences, is cognitively useful in the world, and/or is the end result of a self-correcting process of inquiry. The statement “The snow is white” is true only if its being true is cognitively useful in the real world, and/or if its belief is the end result of a systematic processes of inquiry and debate (scientific, philosophical, or cultural). Pragmatist theory is a more recent approach to defining truth that was made popular in the early 1900s by William James, Charles Pierce, and John Dewey. Different versions of the pragmatist approach often incorporate and do not contradict aspects of the earlier theories based on correspondence and coherence.

Criticism of the theory, notably Bertrand Russell’s, focuses on pragmatism’s emphasis on the epistemology of truth rather than the nature of truth, confusing signs and indicators of truth for the truth itself. A second criticism states that the pragmatist view of what is cognitively useful can differ depending on the person, culture, and time, making it possible for two contradictory ideas to be true.

There exists an alternate view of pragmatism put forth by William Hocking in the early 20th century, known as negative pragmatism. For a negative pragmatist, that which can be proven using the pragmatism criteria still may be either true or false, but something that is disproven is assuredly false. This basic logic underlies much contemporary thinking about scientific experimentation—hypotheses can never be proven, only disproven.

### Deflationary Theories

While inflationary theories hold that truth is a property that a proposition may have, deflationary theories deny this. That is, these theories deflate the importance of the nature and notion of truth. The common ground among all deflationary theories is that whatever entity proves a proposition true or false does not impart any sort of property to the proposition. Furthermore, the predicates “true” or “is true” are superfluous

linguistic constructs. Examples of deflationary theories include redundancy theory and performative theory.

Redundancy theory is the main deflationary theory and it posits that the concept of truth is superfluous, and that saying a proposition is true adds no new information beyond the proposition itself. For example, saying that “It is true that the snow is white” has the same information as saying “The snow is white.” Redundancy theory was popularized by philosophers and logicians in the 1910s and 1920s, including Frank Ramsey and Gottlob Frege. Critics of the theory point to the use of the predicate “is true” in open sentences such as “everything he says is true.” In such sentences the use of “is true” is not redundant and is necessary for the meaning of the sentence.

The performative theory of truth also holds that there is no separate property of truth in a proposition but that the words *true* or *is true* are not redundant because they are informative about the intentions or beliefs of the speaker. The statement “It is true that the snow is white” reveals that the speaker endorses the idea that the snow is white. Performative theory was conceived in the 1950s by Peter Strawson.

The theory’s critics question the shift in focus away from actually defining truth. Instead, the theory emphasizes a speaker’s beliefs, motivations, or intentions. The criticism is that the idea of true and false is a property of a proposition, and a property of a proposition cannot be an action or intention. Another criticism is that adding “is true” to a statement cannot be used to imply intention in other contexts. For example, the statement “please shut the door is true” is unusual and awkward and distracts from the ability to detect that the speaker endorses shutting the door. The simpler statement, “please shut the door,” is more informative about the speaker’s intention.

### Epistemic Theories

The third major group of theories regarding the nature of truth consists of the epistemic theories. These theories define the concept of truth using epistemic ideas such as belief and knowledge. They differ from inflationary theories in that they are antirealist. The concept of truth is not an innate property of objects independent of human

thought but only exists as a construct of humans in relation with the world. Two major epistemic theories are the verificationist and perspectivist perspectives.

The verification theory's major tenet is that for a proposition to have truth it must be verifiable by peoples' own sensory experiences. Anything that is not verified by experience or that cannot be verified is false. The statement "The snow is white" is verifiable, so the statement has the possibility of being true, and can be verified by observing a snowfall. In the verificationist view the statement "the snow is white on a planet on the other side of the universe" cannot be either true or false because it cannot be verified.

Verificationism has its roots with the original empiricists, such as John Locke, and came into its own during the late 1600s to 1800s with philosophers such as David Hume and Auguste Comte. Criticisms of the theory include its inability to deal with vague terms or terms that can have multiple or shifting definitions. For example, the truth of a statement that a given plant is a tree can be difficult to discern given that the definition of a tree is somewhat vague.

The perspectivist theories are a collection of theories based around a similar tenet: that a proposition can only be true according to a specific perspective. Different theories define different perspectives in which truth can be established. These range from the individual perspective, in which truth is only that which is accepted by the individual, to the consensus perspective, in which what is true is defined by the acceptance of all members of the relevant community. Forms of perspectivism have existed since the early Greek Sophists and have been used in the philosophy of Friedrich Nietzsche and the psychological theories of Wilhem Wundt. Critics of this perspective argue that some facts are true no matter what perspective is taken and that their results are nothing more than opinions about truths instead of truths themselves.

### Lay Understanding of Truth

While there has been considerable philosophical debate about the definition of truth (much of it degenerating into pointless semantics), most people know truth when they see it. When given a piece of information people tend to adopt a

correspondence perspective. (Tradition, authority, and consensus also are important sources of presumed truth among laypersons.) If the information matches reality, then it must be true. An explicit truth judgment does not have to be made; it follows automatically from experience. This automatic process only holds when people have prior knowledge of reality, which is occasionally not the case. In situations of ambiguity, when people are not sure of reality, or novelty, when people have no prior experience, explicit judgments of truth are more common. People may use a coherence approach if the information can be smoothly integrated with older information, or a consensus perspectivist approach if the group they belong to has an accepted answer to the truth judgment. The adoption of these alternate truth-seeking approaches, coherence and perspectivist, is driven by a cognitive mechanism known as processing fluency.

Processing fluency is defined as how easily and quickly information is cognitively processed once it is detected by people's senses and how quickly it can be retrieved from memory. Information that has greater processing fluency is judged to be more powerful and more truthful than information with lower processing fluency. When individuals use the correspondence approach, the processing fluency is irrelevant, because no judgment regarding new information has to be made if people have the information already stored. With ambiguous or novel information, processing fluency plays a large role in how much individuals assign truth to the information. Information that easily fits with prior held beliefs or easily fits into mental frameworks, such as with a coherence approach, is processed more fluently and is considered more true than is information that conflicts with prior knowledge. Information that is considered true by members of a group to which individuals belong, such as with the consensus perspectivist approach, is also processed more fluidly than information that is believed by a group to which individuals do not belong.

The source of the information can also have an effect on processing fluency. Sources that are considered credible require less judgment themselves, and the information is processed more fluently. Information that is obtained from an in-context

source also speeds up processing (for example, obtaining historical information from a history book rather than from a cartoon).

How the information is presented also affects truth judgments. Information given in concrete language is more easily processed than information in vague or abstract language. Simple repetition leads to what is known as the truth effect: the more times individuals hear a piece of information, the more they believe it to be true because the processing becomes more and more fluent with each repetition. This effect can be strong enough to override nonrepeated information from credible sources or that goes against group-held beliefs.

Finally, the judge's mood can also affect a truth judgment. Being in a bad mood signals the brain that something is wrong and that extra processing power should be devoted to the external world and incoming information. This extra focus on the external reduces reliance on internal information factors, such as processing fluency, and can negate its effects on judgment.

### Conclusion

While contemplating the definition of truth may fall primarily within the purview of philosophers, the application and belief in the concept is vitally important to every person individually and to the functioning of society at large. Many societal institutions, such as those focusing on educational, legal, and scientific pursuits, take it for granted that truth is discoverable. These institutions are predicated on the belief that truth can be revealed. On the level of the individual, truth is just as important to a normal and functional life. Without assuming some inherent truths, people's cognitive resources would be overwhelmed with constant truth judgments. Nevertheless, the idea of truth is so central to human experience (and, yet, so enigmatic) that it has been debated for millennia. Although there are many conflicting theories about the nature and definition of truth, none of the adherents of these theories can deny that the idea of truth is integral to the human condition. Truth is out there. But where?

## Truth Bias

Researchers have consistently found that people are poor at detecting deception. One reason for this poor performance is the reliance on heuristics or simple decision rules when processing social interactions. Heuristics are mental shortcuts or rules of thumb based on experiences that often result in a quick and satisfactory outcome with minimal cognitive effort. One of these heuristics is the truth bias. The truth bias is the presumption of truth in interpersonal interactions and the tendency to judge an interpersonal message as truthful rather than deceptive, irrespective of the actual truth of the message. Communicators are initially assumed to be truthful, and this assumption is possibly revised only if something in the situation evokes suspicion. The truth bias is important for maintaining relationships and increasing intimacy because accusations of deception are damaging to relationships.

The truth bias is robust and widely documented by research involving people interacting with both friends and strangers. Although researchers have consistently found a strong truth bias in laboratory experiments, they have argued that the truth bias is probably even stronger in

naturally occurring settings because simply asking people to make judgments about deception in a lab context may arouse suspicion and lower a person's natural truth bias. The truth bias also is stronger during face-to-face communication, when people are interacting with friends rather than strangers, and when people do not know that the experimental task involves detection of deception.

Cognitive heuristics like the truth bias are learned through experience or conventional beliefs. Relying on heuristics reduces cognitive effort and simplifies decision making; while heuristics can often lead to a correct decision or judgment, they can result in biases and faulty judgment. In the case of the truth bias, the large majority of naturally occurring interpersonal interactions are truthful, so reliance on the truth bias generally results in accurate judgment with minimal need to assess the interaction for deception.

### Research on Truth Bias

Research has consistently found most people's level of lies in everyday interaction is very small (one to two lies daily), so heuristic use of a truth bias should result in high accuracy in determining truth of interactions with little cognitive effort. However, reliance on the truth bias results in faulty judgment when one accepts deception as truth without appraisal and analysis, and the use of the truth bias results in low accuracy in experiments in which only half the interactions are truthful.

The truth bias has often been measured in experimental designs in which the receiver of messages judges messages that are created with a 50/50 probability base rate of truths and lies. In this context, the truth bias is the tendency to judge over half the interactions as truths, and some researchers have argued that any tendency to judge over half the interactions as truth is a truth bias. However, others have suggested that truth bias depends on base rate. Therefore, if actual truths within a sample occur at a rate of 80 percent, then the truth bias would be any tendency to judge over 80 percent of interactions as truthful.

This issue of the base rate of truths has implications for how the truth bias contributes to the veracity effect. Truthfulness of the message

predicts accuracy because people are more likely to judge a message as truthful. Because of the truth bias, truthfulness of the message is the best predictor of accuracy in detecting truths and lies. In research, people consistently are more accurate at judging truths than lies. Therefore, changes in the base rate of truths can change detection accuracy, and as the base rate of truths increase, so does accuracy in overall detection. For example, research with the 50/50 base rate of lies and truths has consistently found that people are accurate at detecting truths and lies at a rate of around 56 percent. However, increasing the base rate of truths to 75 percent increases accuracy to 60 percent. Conversely, reducing the base rate of truths reduces accuracy. With a 25 percent base rate of truths, accuracy declines to 40 percent.

Arousal of suspicion by telling people of the possibility of deception can lower the truth bias. Further, some researchers have documented that certain professions (police officers or interrogation professionals) or populations (the incarcerated) may actually have a lie bias and expect that people are lying to them. Others have speculated that certain situations (for example, Internet requests from strangers for money) may lower the truth bias. If a receiver perceives that a sender has a strong motive or monetary incentive to deceive, then the truth bias is decreased.

### Two Mental Systems

Research on the truth bias fits into the conceptualization of the mind being driven by two mental systems: System 1 and System 2. System 1 operates spontaneously and quickly with little or no effort or control; System 2 is effortful and systematic mental activity. System 1 accepts information and suggestions presented to it; it is biased toward belief and is gullible. This is based on Baruch Spinoza's theory of belief. People initially have to believe a statement before they can decide to doubt it, and belief is often spontaneous.

While System 1 effortlessly and involuntarily accepts information as true, System 2 must "unbelieve" the information through a conscious and effortful process of doubt and suspicion. Because System 2 is effortful and requires conscious attention and concentration, it cannot operate well when a person is distracted, tired, or has depleted his or her stores of mental energy. For example,

researchers have found that people are more likely to believe dubious persuasive messages when they are tired or accept false statements as true when distracted with another task.

Research on System 1 suggests that the truth bias is a spontaneous process and outside people's conscious control. Efforts to curb the truth bias require System 2 processing, but researchers have consistently found that people are cognitive misers and prefer to engage in less effortful processing. Therefore, the truth bias has a robust and powerful effect on people's perception of information and social interactions.

## UFOs

Unidentified flying objects (UFOs) are mysterious objects seen in the sky, usually at night. Those who claim to have observed UFOs have said that they were seen landing, hovering near the ground, or flying away into the sky. In addition to reports of visual observations, UFOs have been photographed or recorded on radar.

In the 1940s and 1950s, UFOs were often referred to as “flying saucers” because to some people they seemed to be shaped like a saucer or a disk. The term *UFO* was created by the U.S. Air Force in 1953 because UFOs were also observed in other shapes. In addition, UFOs were observed as aerodynamic vehicles engaging in flight dynamics that were unlike those of known aircrafts or missiles.

UFO studies by the United States have included the Robertson Panel, Project Blue Book (previously Project Sign and Project Grudge), and Project Twinkle. The Robertson Panel (1953) was a scientific investigation that was conducted in response to a Central Intelligence Agency (CIA) review of the U.S. Air Force’s Project Blue Book.

The U.S. Air Force conducted a series of investigations in the 1940s and 1950s that were compiled as Project Blue Book from earlier investigations. These were Project Sign (official investigation of UFOs ca. 1948) and Project Grudge, conducted

mostly in 1949. After investigating thousands of UFO reports, the results were published in the Condon Report in 1969. Project Blue Book ended in January 1970 because the U.S. Air Force concluded that nothing substantial could be found to support claims that UFOs were anything other than visual anomalies.

In addition to investigations conducted by the United States, other countries have sought to explain UFOs. The countries that have investigated UFOs include: Belgium, Brazil, Chile, France, Japan, Mexico, Spain, Sweden, Uruguay, West Germany, and the former Soviet Union. The Swedes conducted an investigation of “ghost rockets” between 1946 and 1947. Canadians researched UFOs in Project Magnet between 1952 and 1953, but the project has never been made public. The Brazilian Air Force conducted Operation Saucer in 1977. The French government has had an ongoing program since 1977, and Uruguay opened an ongoing search for UFOs in 1989.

### Private Investigations

Private individuals and groups, dissatisfied with government investigations, have also conducted investigations. One significant individual was Josef Allen Hynek (1910–86). Born to Czech parents in Chicago, he earned a doctorate in astrophysics. He taught physics and astronomy at Ohio

State University. He was recruited by the U.S. Air Force to help with the Blue Book Project and two other projects. Eventually, he became extremely dissatisfied with the manner of UFO research by both the government and the scientific community. As an alternative to the government's investigations, he founded the Center for UFO Studies. Under its auspices, he worked on UFO research for the remainder of his professional life. He at times complained of the mythology, cultism, and conspiracy theories that were often associated with UFO research.

Science fiction has been a popular genre in the post-World War II era. It has often been associated

with conspiracy theories that the government is hiding the truth about UFOs as the vehicles of extraterrestrial aliens.

In 1978, Hynek, along with Drs. Jacques Vallee and Claude Poher, gave a speech at the United Nations (UN) in which they sought to have the UN create a central UFO authority. The speech followed a showing of the very popular Steven Spielberg 1977 movie *Close Encounters of the Third Kind*, in which he had a brief nonspeaking part. The term *close encounters* was taken from Hynek's first book, in which he developed a scale for cataloguing UFO reports.

Other private UFO research organizations in the United States include the Mutual UFO Network, National UFO Reporting Center (NUFORC), Fund for UFO Research (FUFOR), and International UFO Congress. Hynek referred to the rise of an "invisible college" of UFO researchers. One such group is the Aerial Phenomena Enquiry Network (APEN). Its members are unknown to one another. They engage in regular research but keep their contacts with each other via letters or mailed tape recordings. Their contact information is never revealed.

Because it is the duty of the U.S. Air Force to protect the United States, UFOs are investigated. Most have an explanation. The cause or nature of some UFO sightings has never been fully explained. Cold War tensions made investigation important because of their security potentials. Both military and civilian studies of UFOs have sought explanations. Between 1952 and January 1970, the USAF systematically studied UFO sightings. It concluded that most could be explained as misinterpretation of weather phenomena, the results of mild forms of mass hysteria, publicity-seeking hoaxes perpetrated by persons either known or unknown, reports by people with psychological problems, or stemming from conventional objects such as a jetliner that reflected light in an unexpected manner.

### Conspiracy Theories

A variety of conclusions have been reached about UFOs. Some studies have concluded that UFOs do not pose a security threat and are not of scientific interest. Other studies reached different conclusions. The studies that have concluded that UFOs lack scientific interest or military

Unidentified flying object (UFO) shapes are catalogued in this 1969 UFO Sightings Chart from the Royal Air Force. Numerous countries have sought to explain UFO phenomena, most of which have a natural explanation.

significance reached this conclusion after extensively investigating eyewitness claims of sightings, photographs, and other information. The studies concluded that UFOs were not creditable as proof of extraterrestrial beings. However, others have seen UFOs as unsolved scientific mysteries that deserve further study.

Because UFOs have not been explained in a manner that removes all doubt that they are not vehicles from outer space, many people have concluded that the government, the United States in particular, is lying about UFOs. Many believe that their government is engaged in a conspiracy to hide the truth.

Feeding the conspiracy theories are claims that the government is hiding something. All evidence contradicting the conspiracy theory is interpreted as part of the government's denial—a denial that is really a lie on the part of some segment of the government. Supporting claims of a government cover-up are documents withheld on grounds of national security for decades until officials are forced to reveal them by the federal courts in Freedom of Information Act lawsuits. Even then, the documents were usually censored.

The released documents were censored to protect alleged sources and methods that cannot be revealed by law. However, instead of using a black marker to blot out the information, a white pen was used. When displayed on television (old black-and-white or modern color), the white censoring does not show up very well. Using the whiteout marker just fuels the suspicions of conspiracy theorists. In addition, the suspicion that the government is lying is also fueled by the question that if there are no UFOs, then why file reports of UFOs under UFOs?

UFO reports are also made by non-American pilots. Other reports of UFOs have been made by people in many foreign countries. Around the world, people who have spotted UFOs have often come to the same suspicion of their government—it is lying about UFOs and is therefore engaged in a UFO conspiracy.

Supporting the UFO conspiracy theorists are allegations by people in the U.S. space programs. Edgar Mitchell, the sixth man to walk on the moon, is reported to have issued a call for the federal government to end the silence on the existence of UFOs. Besides his astronaut accomplishments,

he holds a doctorate in aeronautics from the Massachusetts Institute of Technology. Other people who have been reported to have made statements that support the claimed existence of UFOs are from the intelligence agencies and civilian and military security organizations.

Roswell, New Mexico, was the site of an alleged flying saucer crash in 1947. Newspapers carried the story. However, conspiracy theorists believe that a government cover-up operation was almost immediately deployed to hide the truth. The military claimed that the event involved weather balloons, but others believe that the extraterrestrials were hidden from the public by means of government lies because it has a secret agenda.

Another event occurred when an object alleged to have been a UFO-shaped object was found in the Baltic Sea. Reports claim that it was found at the end of a 1,000-foot runway. Another UFO event brought charges that the National Aeronautics and Space Administration (NASA) lied in 2012, at a panel in Las Vegas composed of Charles Halt, a former U.S. Air Force Colonel, two other officers who were part of the Blue Book investigations, and a former investigator for the British Ministry of Defense. The panel, *Military UFOs: Secrets Revealed*, drew a crowd that heard Colonel Halt accuse the federal government of a UFO cover-up in which the federal government is hiding extraterrestrial visits by alien creatures.

Charges that governments around the world are hiding the truth about UFOs have been around since the beginning of UFO investigations. Aiding the suspicions and conspiracy theories are mass observations of UFO phenomena, such as a 1989 sighting in Belgium. That the government had nothing concrete to report about the sighting has led some to conclude that the denial of any definitive finding by the government is a lie or a cover-up. In the Cold War era, the tension between the West and communist governments was held up as the reason for the failure of governments to be forthcoming. However, since the end of communism as a dominant force, efforts to force government UFO secrets into the public light have not yet yielded proof of the existence of UFOs and extraterrestrial life.

Many conspiracy theorists believe that governments have been inept in their scientific investigations. Some UFO believers also claim that the

government is lying because it is afraid that if the public learns the truth about the existence of UFOs, there would be mass panic.

## Urban Legends

Urban legends may be deceptive but they are not lies. This odd claim results from the fact that those who transmit urban legends do so in the belief that they are telling the truth—usually to a friend. So if a lie is “an intentionally false statement,” then urban legends are not lies. On the other hand, urban legends may be deceptive because they assert that some event happened when, in the case of most legends, it did not. Some small percentage of urban legends recounts events that actually did happen at one time and place. What really happened once in one place becomes an urban legend when presented as happening at many times and locations. In that way urban legends do deceive; they promote a false picture of reality.

Not all deceptions presented in urban legends are harmful; some stories offer good advice, even if from false premises. For example, “The Kidney

Thieves Legend” tells of a young man who goes clubbing and ends up going home with a woman he met. In the morning, he wakes up in a bathtub packed in ice with a fresh incision in his side and a note advising, “CALL 911 OR YOU WILL DIE.” In this tale, one of his kidneys was removed for sale on the black market. While the story is not true, it does offer useful advice discouraging random sexual encounters.

Modern society uses the phrase “urban legend” often and quite loosely. The term originates from the field of anthropology with the work of folklorist Jan Harold Brunvand of the University of Utah. Brunvand’s popular books on urban legends, beginning with *The Vanishing Hitchhiker* (1981), brought the topic into public consciousness. More books, movies, and songs followed and further popularized these ideas. The rise of the Internet and Web sites such as Snopes.com and About.Com has made the subject of urban legends nearly ubiquitous.

It is important to recognize that the process of circulating and believing urban legends is entirely divorced from the public’s fascination with the topic. When people refer to a story as an “urban legend,” they have made it an object of study but not of belief. When people hear of a legend, they often say, “How could anyone believe that?” because in hindsight they think they would not fall for it. People often feel superior, but the fact is that there are other urban legends they do believe in; they just do not label them “urban legends” but rather see them as safety tips, words to the wise, and other guidelines.

### Definition of Urban Legends

What are urban legends? They are examples of folklore usually conveyed orally. Legends are memorable, repeatable, and appropriate in some common social settings. The content of an urban legend is believable, features actions of regular people, and takes place in the recent past. The sender and receiver of a legend usually come from the same locale and generation. The legend’s action that is recounted happened “around here” but to a friend of a friend, an unnamed, near-acquaintance folklorists call FOAF.

Legends are composed of central elements and peripheral details. The core of the story does not change; it contains the emotional power of the

legend. Around this core are details which may be adapted frequently to suit the story to the immediate locale. For example, in three classic urban legends—"Kentucky Fried Rat," "The Procter & Gamble Trademark," and "The Slasher Under the Car"—the core elements include a fast-food franchise and a rat, a demonic cult and a TV talk show, and a shopping mall and undercar slashers, respectively. Legends are localized and modified in the retelling, so the particular restaurant franchise, television talk show, or mall may change to present a locally significant landmark or popular talk show without changing the power or effect of the legend. Folklorist Brunvand recaps the appeal of urban legends: "Legends survive by being as lively and 'factual' as the television evening news, and, like the daily news broadcasts, they tend to concern deaths, injuries, kidnappings, tragedies, and scandals."

A common and perplexing question is: Where do urban legends come from? For all of the detailed folklore investigations, there are only conjectural answers. Folklorists specialize in tracing stories back through a chain of tellers in an attempt to find ground zero—the point of origin for a particular narrative. Rarely do they succeed; they usually find that the origins of the tale vanish in the mists as the researcher pursues, but never finds, the FOAF. The best theory about the origins of urban legends suggests that people may overhear and misunderstand someone who is speaking hypothetically: "What would happen if people tried to steal organs for the black market? How do you think they'd do it?" Then the overhearer recounts those conjectures as fact, and the story is out in circulation.

Not all stories that are picked up through urban-legend processes endure. Individuals know about a great many that become popular and circulate far and wide. There is no way of estimating how many less compelling stories are put into circulation only to sink because of popular indifference. This result is usually the fate of urban legends that someone tries to fabricate to prove a political point or harm a commercial rival.

### The Power of Urban Legends

The legends that attain the height of popularity have a narrative power that their unsuccessful cousins lack. Narrative theory points out

that individuals believe stories that have two qualities: they make sense internally, that is, they hang together as stories, and they make sense in people's world, that is, people can imagine them happening. Urban legends that capture the public imagination satisfy both of these tests. This fact means that analysts can track the public mood in a community by attending to which urban legends are circulating. Some legends highlight tensions in race relations, others reflect economic uncertainties; the point is that popular legends present a snapshot of the community's unconscious.

Insights from folklorists can help religious, government, and law enforcement figures understand the worries coursing through the community. Most stories in the legends are not factual, but telling these stories to their friends allows members of the community to give voice to their fears without having to admit to them. In this way, circulating these narratives through their social networks becomes a therapeutic process.

The fundamental power of urban legends is in their utter believability. The tales are told and retold as true with never a discouraging word. This persistent popularity is due to the fact that these are good stories; they have rising and falling action, they accurately depict the human condition, and there is an outcome which reinforces a moral value. If these events did not actually happen, one can say that they might have happened and, in some cases, even that they should have happened.

The function of urban legends is significant even though they are not literally true; legends are used by individuals and groups to explain their world to each other and to create social solidarity. The action of sharing an urban legend creates a larger, social form of truth which transcends the particular facts of the narrative—creating a practical moral for the story—and providing a social reward for telling the story. The social truth and the reward combine to explain why and how this phenomenon endures.

Legends tell people who the good and bad people are and what they did to earn those designations. The three urban legends mentioned at the outset have bad portents: tainted food, demonic influence, and felonious assault. However, there are many legends with a more positive spin: "The Obligatory Wait" (tolerance for tardy professors);

“The Mexican Pet,” (careful attention to imported goods); and, “Curses! Broiled Again!” (safe use of tanning beds).

Urban legends are popular because the story is compelling and delivers a subtle but useful message, and in this process no one actually suffers the injuries described in the story. Even the three initial stories offer useful moral guidance: “Kentucky Fried Rat” (people should pay more attention to who prepares their food and how); “The Procter & Gamble Trademark” (individuals need a way to understand the existence of evil in the world, and/or, beware of the actions of giant corporations); and “The Slasher Under the Car” (pay attention to the surroundings in public places, especially during the holiday season).

### Urban Legends in Film

Although urban legends move primarily through face-to-face encounters, the frequency with which they occur as elements in popular films is noteworthy. This phenomenon seems to reinforce the narrative power of the legend. The story is so good that it wants to be told. For example, in the film *The First Wives Club*, the urban legend known as “The Philanderer’s Porsche” is replayed. In the legend and the film a husband is leaving a wife of long-standing for a younger woman (his nurse, his secretary); he tells the wife to sell the car and forward the money. In the urban legend an advertisement offers to sell an “almost new” Porsche for \$50. An eager sports car buff answers the ad, inspects the car, and pays the \$50. He then begs to know the facts that produced this incredible bargain. That is when the “and send me the money” punch line is sprung.

In the film version, the car is a Lamborghini, the price is \$1, and the shunned wife keeps 50¢ as her part of the sale. She recounts the sale to her husband in person as she hands him two quarters as half of the proceeds. He is in anguished disbelief; she tells him that she feels his loss and hands him her two quarters to ease the pain. The tasty blend of justice and revenge that is the hallmark of several urban legends is clearly presented in this case.

The vacation film series from *National Lampoon* has made frequent use of urban legends, for example, *The Runaway Grandmother*, in which a grandmother dies on a trip and no one in the

family knows what to do, so they tie her body to the roof of the car. Then the car is stolen. In fact, a film—otherwise unremarkable—has been made on the premise that the main character is a sociologist investigating urban legends and stumbles into a world of evil beyond her grasp. The title for this shaky premise is *Candyman*. In summary, there is a mix of personal and mediated modes of distribution for urban legends.

### Subjects of Urban Legends

Urban legends touch upon many topics. In addition to business and industry, Brunvand’s categories include “classic automobile legends,” “dalliance, nudity, and nightmares,” “the hook and other teenage horrors,” “academic legends,” “sex and scandal,” “contaminations,” and “other legends of accidents and mishaps.” Legends that are directed at corporations are tales such as “The Red Velvet Cake” and its cookie recipe variations; their payoff is revenge against overbearing institutions. “The Procter & Gamble Trademark” legend with all of its devilish implications suggests that at least one corporation is in league with the devil. In “The Economical Car” listeners learn that an experimental, highly fuel-efficient car has gotten away from the factory by mistake. The manufacturer gets its unwitting owner to allow a switch so that the car’s revolutionary secrets are once again hidden by the automobile and petroleum industries.

The oldest urban legend in the United States is “Petition to Ban Religious Broadcasting.” The legend continues to stimulate public concern today. The premise is that the Federal Communication Commission (FCC) has received a petition (Number 2493) that proposes to ban religious programming on television. The rumor has its roots in rumors about atheists, especially Madalyn Murray O’Hair, and generated 30 million letters of concern from 1975 to 1995.

Regarded as the second-oldest urban legend in the United States, “The Procter & Gamble Trademark” legend has enjoyed wide circulation. The story is that the chief executive officer (CEO) of Procter & Gamble (P&G) announced on a television talk show that his firm was giving a portion of its proceeds to Satan. The salient line from the CEO, repeated in the legend’s retelling, is: “There aren’t enough committed Christians now to make

Artist Tom Otterness created a tribute to the New York “alligator in the sewer” urban legend in his “Life Underground” sculptures, which are scattered throughout the subway platforms at 8th Avenue and 14th Street in New York City. In 1935, as legend has it, an alligator crawled out of a manhole in Harlem and was promptly beaten to death. Inflated by Robert Daley’s 1959 book *The World Beneath the City*, the story grew into a scientifically implausible legend about alligators swarming through New York’s sewer system.

any difference so I can tell you . . .” P&G has fought this legend for decades through public information efforts and even in court actions. Circulation through the Internet means that people read this legend for the first time every day, despite P&G’s efforts to eradicate it.

What follows is a current inventory of eight very popular urban legends; as would be expected, this listing will change over time, but these are all classics of popular culture. “The Kidney Heist,” explained above, is the most popular of current urban legends. The premise of the “Automatic 4.0 Legend” is the answer to the question: What happens to someone in college if their roommate dies? The fictional answer is that the bereavement policy of the college dictates that the student with the dead roommate receives a 4.0 grade point average, that is,

straight As. In some versions the policy applies to suicide, in others to any sort of death.

“Mr. Rogers was a Navy Seal” is a legend that feeds on the juxtaposition between the friendly figure of the Public Broadcasting System children’s show and the fierce commando. Supposedly, Mr. Rogers served in Vietnam as a sniper. Some versions of this baseless tale suggest that he wore tennis shoes on the TV program to hide tattoos from his service years.

A classic of the genre is the “Bloody Mary” urban legend. In this tale, the name is repeated three (or 13) times in a darkened room in order to conjure the ghost of a witch to appear in a wall mirror. The “JFK/Jelly Doughnut” legend asserts that the former president John F. Kennedy declared himself to be a pastry while addressing the citizens of Berlin in 1963. In fact, JFK said, “Ich bin ein

Berliner,” which translates to “I am a citizen of Berlin.” The noun “Berliner” is close to the name of a favorite local pastry, but the president was not laughed off the stage as the legend has it; in fact, Berliners understood and embraced his message.

Another popular subject of urban legends is the soft drink Coca-Cola. Stories about this beverage are known collectively as “Cokelore.” Perhaps the most famous legend in this genre regards the children’s candy Pop Rocks. The legend held that eating the candy and then drinking the carbonated beverage would cause damage to a child’s stomach.

The “Good Samaritan” urban legend has been applied to many celebrities. In essence, it tells of a person stopping to help another change a tire under difficult circumstances. The person helped asks for the Samaritan’s address in order to send a thank you note. What arrives instead of a note is a color television, a \$10,000 check, or the payoff on the Samaritan’s mortgage; it turns out that the person helped was a celebrity such as Bill Gates, Nat King Cole, or Donald Trump.

The “Alligators in the Sewers” urban legend tells of these predators lurking in the New York City sewers. They got there after being flushed from homes and apartments of individuals who bought small alligators on trips to Florida. As they grow, they become a problem, so people use

the handiest means available to rid themselves of the animals: They let the alligators live in city sewers, becoming more daunting as they grow.

## Veracity Effect

The Veracity Effect refers to the observation made by Timothy R. Levine, Hee Sun Park, and Steven McCornack that deception detection accuracy depends on the veracity, that is, the honesty, of the message being evaluated. Research shows that when deception detection accuracy is scored separately for truths and lies, people tend to get truths correct more often than lies. That is, people are probabilistically more likely to be correct in presuming honesty than they are in correctly identifying a lie as a lie. As a consequence, the honesty or dishonesty of a message affects the likelihood of the correctness of a perception of honesty.

The veracity effect results from truth bias, which is the tendency to believe someone more often than not regardless of whether or not a person is actually honest. Truth bias is a very typical finding in deception detection research. Because people tend to believe others, when others are honest people tend to be correct in presuming honesty. Lies, however, are more often mistaken for the truth. This creates the veracity effect.

A coin-flipping analogy helps explain the veracity effect. If someone trying to guess the outcome of a sequence of coin flips guesses heads more often than he or she guesses tails, they are more likely to be right on those occasions when heads is obtained. When tails comes up, however, they

tend to guess incorrectly. In this analogy, heads is like judging honest messages and tails is like judging lies. Because of probability and chance, truth-biased people are more likely to be right about truths than lies.

### Implications of the Veracity Effect

The veracity effect is very well documented in experimental research on deception detection. In meta-analysis, people are truth biased in more than 70 percent of research studies, and on average, 57 percent of all messages are believed in deception detection experiments. Deception detection accuracy averages 54 percent in terms of correct truth-lie discrimination, but accuracy for truths averages 61 percent compared with 47 percent for lies across prior studies. The veracity effect is the label for this typical difference in truth and lie accuracy.

A primary implication of the veracity effect is that because people are statistically better than 50/50 chance at truth-lie discrimination (54 percent overall), this does not mean that they are above 50 percent at detecting lies per se. Truth-lie discrimination is an average across truths and lies. The 61 percent for truths and 47 percent for lies, when averaged, yields 54 percent ( $61 + 47 = 108$ ;  $108 \div 2 = 54$ ). This makes average truth-lie discrimination potentially misleading. Consequently, following the discovery of the veracity effect,

many researchers report accuracy for truths and lies separately in addition to reporting average accuracy.

A second important implication of the veracity effect is that the truth-lie base rate matters. The truth-lie base rate refers to the proportion of truths and lies judged in a deception detection task. Most deception detection research uses an equal number of truths and lies. Such research yields the 54 percent accuracy result mentioned previously. However, because accuracy is typically higher for truths than lies, the greater the proportion of truths judged, the higher the accuracy. Conversely, as the number of lies exceeds the number of truths, accuracy decreases.

The effects of truth-lie base rates on accuracy can be predicted with the Park-Levine Probability Model. The model, which rests on the veracity effect, predicts a linear relationship between deception detection accuracy and the truth-lie base rate. As long as people are truth biased, the greater the proportion of messages that are honest, the higher the accuracy. Further, the more truth biased people are, the larger the base rate matters.

A third implication of the veracity effect is that variables in deception detection research that affect truth bias affect truth and lie accuracy but do not necessarily impact overall accuracy. A variable that increases skepticism and lowers truth bias will tend to reduce accuracy for truths and increase accuracy for lies. However, the increase in lie accuracy and the decrease in truth accuracy typically cancel out when overall accuracy is calculated. Thus, one type of error is traded for another. Consistent with this, meta-analysis reports that truth bias and correct truth-lie classifications (that is, overall accuracy) are not correlated.

For example, suspicion tends to reduce truth bias. When people are suspicious, they are less likely to believe others. Suspicious people are less likely to fall for lies, but they also are more likely to mistake honest messages for lies. The net result is that suspicion has little impact on overall accuracy.

A final implication of the veracity effect is that deception detection may underestimate overall accuracy. The base rate in most deception detection experiments is 50/50 truths and lies. But

outside research settings, truthful messages tend to be more prevalent than lies. If this is the case, then because people are typically truth biased, they may be more accurate than the 54 percent research average suggests.

## Vietnam War

Many Americans will argue that the Vietnam War presents a classic example of lying and deception, in which citizens were told lies about the cause of the war, the occurrences during the war, and how the war concluded. During the war itself, military officials made clear, strategic choices that capitalized on the ability of American leaders to

*A South Vietnamese soldier beats a farmer with the end of a dagger for allegedly supplying government troops with inaccurate information about the movement of Viet Cong guerrillas in a village west of Saigon, Vietnam, January 9, 1964. The Vietnam war was rife with lies and deception from its inception to the atrocities committed to its conclusion.*

manipulate the truth in order to garner strategic advantages as they waged combat in Southeast Asia. The Vietnam War occurred in Vietnam, Laos, and Cambodia between 1955 and 1975. It was fought between North Vietnam (who was supported by a series of communist allies) and South Vietnam (backed mainly by the United States and other anti-communist nations around the world). Most of the fighting occurred between the Viet Cong (a communist group located within South Vietnam) and the United States.

Given the lack of arms available to the Viet Cong, they typically participated in guerrilla tactics. The United States, on the other hand, depended on air superiority and firepower to wage its side of the war. The United States became involved as part of its larger containment strategy, aimed at limiting the spread of communism; the North Vietnamese, on the other hand, saw the war as a colonial conflict against France. By 1968, American involvement had peaked, and troop levels steadily decreased until August 1973, when U.S. military involvement came to an official end. The number of casualties across all sides is estimated to be between 1 million and 3.7 million.

### **American Deception During the War**

The Magic Eye was part of perhaps the strangest deception campaign during the Vietnam War. The Magic Eye was developed in 1967 and served as a device to help in detecting the presence of Viet Cong. Rudimentarily designed, it consisted of two boxes with an impressive number of lights, horns, antennae, dials, and gauges. Citizens were told that the device could tell who was a member of the Viet Cong and that anyone who confessed would be treated well. When someone who was known to be a member of the Viet Cong walked between the boxes, an American soldier would flip a switch and set off the horn and lights. While the Magic Eye did not work particularly well (or for very long), it did lead to some unknown Viet Cong members admitting to their allegiances when confronted with the box.

In a similar vein, American soldiers began utilizing people sniffers, which allowed machines to find organic smells (such as ammonia found in sweat and urine) to point out where the Viet Cong might be hiding. Helicopters were manufactured with two air scoops that would bring air into the machines and permit pilots to detect what smells were in the air. From a deception perspective, once enemies were allegedly located, the U.S. military would drop pamphlets that warned of an eminent artillery attack in the area. Loudspeakers would also be used to send the same message. Once an offensive action took place, more pamphlets were used to urge survivors to support the government of South Vietnam and leave the Viet Cong behind. In terms of success, the Viet Cong prevented people sniffers from having much impact. Once they realized that

the sniffers sought ammonia, they began leaving buckets of urine and other waste products in one area before moving away to a safe spot.

According to author Seth Jacobs, another unique deception effort was waged by General Edward Lansdale. He utilized rumor campaigns in Hanoi that attempted to convince locals that Chinese soldiers were raping Vietnamese women and that China was planning to take over all of Vietnam as soon as the war concluded. As part of this plan, Lansdale created pamphlets to be used in North Vietnam that talked about monetary changes, work camps, and confiscation of personal property under the impending Chinese rule. Even more brazenly, according to Jacobs, he designed materials telling the North that the United States was preparing to launch atom bombs in the region. In terms of success, around a million North Vietnamese fled to South Vietnam after hearing about Lansdale's "facts." Whether it helped the war effort in any meaningful way, however, is still up for debate.

### Media Deception

When looking at deception during the Vietnam War, no episode seems to have attracted more media attention than the creation and subsequent airing in 1982 of *The Uncounted Enemy: A Vietnam Deception*. The program asserted that intelligence officers working under U.S. general William Westmoreland in 1967 intentionally manipulated intelligence estimates to show that there were far fewer communist personnel in South Vietnam than there actually were. By doing so, they hoped to show that the war was being won in order to instill faith among American citizens that the United States was pursuing the right course of action.

In response to the program, Westmoreland sued CBS (Columbia Broadcasting System) and those involved with the program for libel to the tune of \$120 million. Before going to trial, however, Westmoreland dropped his suit, claiming he had interpreted a statement from the network as an apology. CBS, however, still lost its libel insurance and was forced to scale back the tone of its investigative reporting as a result. The lawsuit created a volume of literature, as well as critical discussion, about ethics, free speech protection, libel, and the politicization of news.

*The Uncounted Enemy: A Vietnam Deception* declared that the 1968 Tet offensive came as a

shock to Americans because U.S. military officials in South Vietnam had previously, arbitrarily, and willingly reduced the number of enemy troops. In short, leaders decided that 300,000 would be the ceiling in terms of enemy troops reported in order to make it seem like the United States was doing better than it actually was. Perhaps most seriously, the 90-minute program directly charged that intelligence officers deleted databases to hide the deception.

From a network perspective, the producer, George Crile, violated CBS network policy and practices by intentionally avoiding interviews with anyone who would contest his argument, and then manipulated longer answers into sound bites to help convey his story. Looking at Westmoreland and Crile, it appears they were both at least marginally guilty of attempting to deceive the American public for their own reasons. Westmoreland was aware of growing tensions domestically and an antiwar fervor, while Crile wanted to bring out the negative aspects of the war and draw attention to citizen concerns.

However, it was not just this one episode that generated questions about the media's impact on Vietnam. With the media having no restrictions and being permitted on the front line of the battlefields, they were able to show Americans exactly what was going on every day—or at least what they wanted them to see. Again, the Tet offensive serves as a prime example. Tet began on January 21, 1968, when the North Vietnamese launched attacks on numerous major cities in South Vietnam. In the beginning, the offensive was blocked well by American and South Vietnamese forces, and there were minimal casualties.

Yet news coverage failed to mention this and instead focused on the shooting down of four American AC 130s gunships in Khe Sanh. The footage of the plane crashes showed fire, disaster, and death, which sparked protests throughout the United States. Why was the focus on Khe Sanh instead of Tet? Largely because it was far easier to access, and the drama around the plane crashes made for better television.

When it comes to media coverage, there are questions about what classifies as deception and what is nothing more than editorial decisions. But in the end, the American public was receiving a distorted view of what was occurring in Vietnam

during the war effort. In World War I, the military and government had total control over the press. They were able to prevent pictures of wounded soldiers or of death. If anything, the media worked as a propaganda arm for the military—helping spread a message of hope and support throughout the country. But during the Vietnam War, control and censorship were minimal. Instead, Americans saw exactly what the media wanted them to see (for better or worse).

A good example involves the events of the My Lai massacre in March 1968. American soldiers—led by Lt. William Calley—attacked a village supposedly full of Viet Cong soldiers. The particular soldiers had previously fallen victim to numerous guerrilla attacks and booby traps. As a result, they were mentally stressed. While they found no Viet Cong soldiers in My Lai, the Americans killed roughly 5,000 innocent villagers, including women and children. At first, the media reported the government's message that a large number of Viet Cong soldiers had been killed, while some citizens were lost as collateral damage. When the truth came out a year later, the American public turned even more sharply against the war efforts. In this case, the media prevented the government from deceiving the general public.

The media—as has been discussed earlier—was not always honest in their watchdog role, however. Consider a famous picture from Vietnam. The photo was shot by Eddie Adams and shows the execution of a Viet Cong guerrilla soldier. The picture was originally used to show that the South Vietnamese were no better than their Northern counterparts. But what the picture leaves out is the back story. It is not just a soldier being executed; it was a general of a small group of Vietnamese soldiers who had just killed the entire family of the man pulling the trigger. Again, editors directly stated that they wanted the picture to speak for itself and did not want the message to be subdued by any explanation or description—even if it ended up sending the wrong message.

### Pentagon Papers

The Pentagon Papers were the hallmark of deception during the Vietnam era. These papers—contained in a U.S. Defense Department study, “United States-Vietnam Relations, 1945–1967: A Study Prepared by the Department of Defense”—demonstrate a

clear pattern of lies and deceit cutting across four presidencies regarding information about activities in southeast Asia. Defense Secretary Robert McNamara was the mastermind behind the report, hoping to leave an encyclopedic volume about the war for individuals in the future.

Most troublesome is that the pattern of lies suggests a systematic effort across many years to intentionally deceive the American public about why the United States was in Vietnam, along with what the United States was doing there. The papers became publicly known in 1971 when published on the front page of the *New York Times*.

An initial finding of concern was that the United States had intentionally expanded the scope of the war by bombing Cambodia and Laos—facts that were never reported by American media. Other previously unknown truths exposed in the Pentagon Papers include that President John F. Kennedy planned to overthrow Ngo Dinh Diem, president of South Vietnam before Diem was assassinated in 1963. Likewise, President Lyndon Johnson had already initiated plans to bomb North Vietnam before winning his election, all while scaring Americans into believing that his opponent—Barry Goldwater—was the one who would utilize bombing campaigns. Further, Johnson sent combat troops into Vietnam on July 17. However, he never met with advisors regarding the decision until the period between July 21 and 27.

In perhaps one of the most embarrassing aspects of the Pentagon Papers, a memo from the Defense Department to the Johnson administration listed five reasons that the United States remained in southeast Asia. The first (accounting for 70 percent of the explanation according to the department) was to avoid a humiliating defeat if the United States were to withdraw. Second—at 20 percent—was to keep the South Vietnamese from falling into Chinese hands. Third, at only 10 percent of the reason, was to permit the citizens of South Vietnam to enjoy a freer, democratic way of life. The memo also goes on to remind the administration that the Defense Department wanted to emerge from the crisis without any unacceptable stigma caused by the methods used to win (in other words, the United States did not want to drop nuclear bombs).

Finally, the memo clearly delineates that the Defense Department did not want to be perceived

as simply helping a friend, which would lead to further calls for American intervention across the globe. Ultimately, the memo showed that the department did not care about the South Vietnamese and was only advocating intense bombing as a means to allow the United States to escape from the war without being humiliated.

The Vietnam War was perhaps the most deceitful military conflict in U.S. history. While World War II may have more directly utilized deceit tactics on the battlefield, the Vietnam War raised public concerns about government lies and deceit, along with issues regarding the presence of a free media to report on whatever they wished without regard to the truth.

## Vocal Stress Analysis

Vocal stress analysis refers to computer-aided technology and techniques for analyzing nonverbal speech in order to aid deception detection.

Modern vocal stress analysis is grounded in paralinguistics, digital signal processing, and machine learning. *Vocal stress analysis* is a term used most commonly in reference to software used by law enforcement as an alternative or complement to traditional polygraph tools for investigations.

To assess veracity using vocal stress analysis software, a speaker's voice is first recorded using a microphone and converted to a digital format on a computer. The vocal recording is then signal processed to extract acoustic features, such as pitch or intensity representations (for example, mean, variance) of each utterance. The utterances generally correspond with a fixed protocol comparable to the Comparison Question Test used in a polygraph. Based on the testing protocol the overall interview is scored and deviances or outliers are identified to assess veracity. This example is a simplification, but it provides the basic principles behind vocal stress analysis—record the voice digitally, extract vocal features, and submit these features to a statistical/computational model to assign a probability of deception.

Vocal stress is a term used almost ubiquitously in academic and professional settings when discussing software for assisting deception detection. However, vocal stress is actually a misnomer, as modern techniques for analyzing the voice analyze more than stress. Modern techniques and technologies for analyzing speech attempt to identify vocal indicators of stress, emotion, cognitions, and behavioral control. For example, paralinguistic indicators of cognitive effort are speech hesitations (that is, response latency) or dysfluencies (that is, the use of the sounds “um” or “er” and pauses).

Vocal analysis confined to stress has intuitive appeal. When a nervous or stressed speaker talks, there is a noticeable increase in the pitch or tremble of their voice. When stressed, individuals' muscles often tighten and clench in response. When the muscles about the vocal folds, which vibrate to affect the air and produce sound, become tense, they vibrate at a higher frequency. The frequency of the vibration or fundamental frequency is what people hear as vocal pitch. Because of the observable variation in speech in response to stress, and the belief that liars faced with consequences are more stressed, the initial focus of vocal analysis was on stress.

### Microtremors and Vocal Analysis

The term *vocal stress analysis* was coined during the initial wave of software marketed to law enforcement. Despite the richness of features present in the voice, this initial software focused on a very small frequency band of 8 to 12 hertz. This is because the human body exhibits periodic contractions of the muscles known as microtremors on this narrow and low frequency range. These early vocal analysis systems attempted, unsuccessfully, to measure this frequency produced by the larynx muscles.

Early vocal analysis systems assumed that a reduction in the power of the microtremor frequency implies deception because it is caused by a stress-induced drop in blood pressure. The microtremors do occur at the low frequency range; however, existing recording technologies may not have the sensitivity required to accurately measure and subsequently calculate this low frequency. Additionally, even if microtremors can be measured via the voice, the relationship between lower blood pressure and deception is tenuous.

The name and any controversy associated with vocal stress analysis software can be primarily attributed to the flawed initial software based on microtremors. The research has consistently failed to reliably detect deception in experimental or field settings using these software tools. It is unfortunate, but understandable that any mention of vocal stress analysis will conjure up memories of this early technology and be met with disdain or a polite grimace.

### Use of Modern Vocal Analysis Software

Despite a checkered history of vocal analysis software, the voice undeniably contains signals diagnostic to deception that people effortlessly decode in everyday conversation. Individuals can recognize when a loved one or friend is angry, sad, bored, or in any number of emotional and cognitive states by hearing them talk over the telephone or in person. The problem is not if the voice is diagnostic to deception but if computers can be taught to decode vocal signals. While some people take this ostensibly simple task for granted, computers have no ears or context and face an uphill battle making sense of speech. Bearing this in mind, one must remain rightfully incredulous of vocal analysis software but be

mindful not to conflate all software and tools as universally invalid, as the technology is steadily improving.

One challenge for deception research when utilizing vocal analysis software is its computational nature; this issue is occurring in all computational nonverbal behavior analysis as well. That is, advanced signal processing of speech signals are becoming black boxes either to proprietary software or esoteric algorithms. In the early days of vocal analysis, most analysis was performed on standard acoustic features, such as pitch, that have a direct physical correspondence to physical vibration of the vocal fold. However, modern vocal analysis applies advanced digital signal processing and machine learning techniques to identify deceptive speech, but it provides no intuitive or theoretical explanation.

A common approach to developing modern algorithms for detecting deceptive speech is to collect a corpus of experimentally manipulated truthful and deceptive recordings. These recordings are signal processed to extract advanced vocal features, understood mostly by mathematicians, and submitted to nonlinear and multidimensional classification algorithms (for example, support vector machines, neural networks). The end result is a black box that predicts deception using speech more accurately than traditional methods but contributes little to theory or understanding.

Two issues further complicate the use of modern vocal analysis software for deception detection. First, the specific lie scenario or situation used as ground truth to train the software cannot be generalized. Using software developed and trained on criminal interviews would not be very accurate for rapid screening or Concealed Information Tests. Second, much to the chagrin of vocal researchers, the voice is not Pinocchio's nose. Some people exhibit many emotional and cognitive indicators in their voice, while others actually improve their speech when lying (for example, politicians). One should not over-rely on any one behavioral indicator of deception nor assume the voice does not reveal cues to deception because it is unequally expressed by all people.

### Conclusion

The voice is very diagnostic of emotions and deception. Despite the checkered past of previous

technologies, vocal stress analysis is improving in accuracy of detection, but at the expense of intuition, generalizability, and universality of expression.

## Vrij, Aldert

Aldert Vrij is an internationally recognized expert in deception. He is a Dutch researcher, author, and since 2000, professor of applied social psychology in the Department of Psychology at the University of Portsmouth, United Kingdom (UK). He has written more than 350 publications, articles, and book chapters describing his research into nonverbal, verbal, and neurophysiological cues to deception and lie detection. Vrij's latest book, *Detecting Lies and Deceit: Pitfalls and*

*Opportunities* (2008), is a comprehensive summary of deception detection research.

In 1991, Vrij earned his Ph.D. at the Vrije Universiteit in Amsterdam in the Netherlands. Four years later, he joined the Psychology Department at the University of Portsmouth and became a senior lecturer before being promoted to a professorship. Since his arrival at Portsmouth, he has coordinated the Psychology and Law Unit and the Social Psychology Unit at the university. He supervises dissertations at the undergraduate level, and he has supervised more than 20 Ph.D. students at the postgraduate level. His research is funded by the UK government, the U.S. government, and the British Academy.

Vrij is the editor of *Legal and Criminological Psychology* and serves on the editorial boards of several journals, including *Law and Human Behavior*, *Human Communication Research*, *Applied Cognitive Psychology*, and *Journal of Investigative Psychology and Offender Profiling*. He is a member of the Board of Governors of the Society for Applied Research in Memory and Cognition. In addition to holding academic responsibilities, Vrij consults with police forces, presents workshops on lie detection to practitioners and scholars, and serves as an expert witness in court. He is the point of contact for the European consortium of Psychological Research on Deception Detection (E-PRODD).

Vrij is recognized for his many contributions to the field of deception and the detection of lies. Most notably, his work has found only a weak association between nonverbal behaviors and deception, an increased need for understanding verbal communication and deception, and a call for additional empirical proof for lie detection tools that produce advances in detection accuracy. He has also called for more research that examines deception in real-world contexts. Unlike many other researchers, Vrij's experiments often involve collecting interview data from suspects in realistic high-stake situations.

Vrij has articulated a frequently cited definition of deception: "a successful or unsuccessful deliberate attempt, without forewarning, to create in another a belief which the communicator considers to be untrue." His definition differs from others because it does not imply that unconsciously misleading other people should be classified as

deception. The definition also emphasizes that attempts to lie that are unsuccessful should still be classified as deception. Vrij has also categorized several motivations for why people lie: (1) for one's own benefit (self-oriented) or for the benefit of others (other-oriented), (2) to gain advantage or to avoid costs, and (3) for materialistic reasons or for psychological reasons.

As a pioneer in the field of nonverbal behavior and deception, Vrij argues that a liar's behavior depends on factors such as interpersonal differences, age, personality traits, and idiosyncratic patterns. Vrij's perspective emphasizes that there is no single nonverbal behavior that is uniquely associated with lying. In a 2000 experiment, he found that at least 70 percent of truths and lies could be correctly classified if a combination of nonverbal cues was examined, rather than examining these clues individually. Identifying nonverbal cues to deceit is a two-step approach, including the recognition of behavior change and interpreting if such changes are meaningful.

Vrij proposes that speech content can reveal deception by reflecting changes in emotions, cognitive effort, attempted control, and psychological distancing. Previous work has asserted that liars are capable of controlling their speech, but Vrij has argued against this assumption. Instead, he maintains that individuals, including professional lie detectors, do not pay enough attention to verbal cues to deception. Vrij has researched a variety of language analysis approaches, including criteria-based content analysis, reality monitoring, and statement validity analysis.

The beliefs that people hold regarding deception and deception cues have also been of interest to Vrij. In addition to concluding that average

citizens are poor judges of veracity, Vrij adds that trained professionals also do not perform well on lie accuracy tasks. In a 1996 study, he concluded that police officers form the same stereotyped beliefs about nonverbal indicators of deception as inexperienced lie catchers. Relying on unproven deception cues indicated that work experience does not yield a better understanding of the nonverbal behavior-deception relationship.

In sum, Vrij contends people can improve their lie detection skills by observing nonverbal and verbal cues more flexibly, suspiciously, and simultaneously.

## ***War of the Worlds***

*The War of the Worlds* is a science-fiction novel written by H. G. Wells and published in 1898. The novel focuses on the adventures of a single protagonist during a time in which Earth is being invaded by violent aliens from Mars. The novel gained significant success and was adapted for a radio broadcast in 1938.

The broadcast, directed by Orson Welles, was aired as an episode of *Mercury Theatre on the Air* (a drama series that aired on CBS's radio network) at 8:00 P.M. on October 30, 1938. The broadcast was formatted to run for 60 minutes, with the first 40 minutes being presented in the form of news reports. Approximately 12 million people listened to the broadcast. The realism of the news reports, coupled with the fact that about one million listeners did not hear any of the disclaimers that had been stated and displayed prior to the broadcast, led many people to believe that Martians were actually invading Earth.

In addition, approximately one month prior to the *War of the Worlds* broadcast, news reporters at radio stations across the country began interrupting programs to inform the American public of the increasing dangers in Europe, describing how Adolf Hitler was rising to power and threatening to invade many countries. In one month, interruptions for news bulletins became

increasingly frequent, adding eyewitness accounts and live interviews. These bulletins became so frequent that when the *War of the Worlds* broadcast occurred, many uninformed people believed that it was another actual news bulletin.

The broadcast began with a disclaimer describing the novel and story. Orchestral music then played for a while, followed by a news anchor's voice interrupting to describe explosions and meteors from Mars. The orchestral music then resumed but was later interrupted by another news bulletin. The story then developed as the Martians landed in Grover's Mill, New Jersey, and began vaporizing humans with their advanced and violent heat-ray technology and toxic hydrogen gas.

Orson Welles, acting as Professor Richard Piereson of Princeton University, discussed the Martian technology, while a news reporter discussed the horrors that the Martians were wreaking on New Jersey and New York. Many other interviews with actors pretending to be astronomy experts, military officials, and the secretary of the interior were played in the broadcast as well. The broadcast also used orchestral music, commercial breaks, and intermissions to add realism.

The broadcast was intended to be an entertaining story in the spirit of Halloween. In fact, after the story had finished, Welles reminded the audience that it was a work of fiction meant to

be a spooky tale for the Halloween season. However, the reaction from the public was one of terror. Many people who listened to the broadcast had failed to notice the many advertisements—including newspaper listings and radio announcements—regarding the upcoming broadcast, and missed the first few minutes of the broadcast introducing the *War of the Worlds* as a novel and fictional story.

This resulted in a mass panic. Trenton, New Jersey, police received 2,000 phone calls in less than two hours. The *New York Times*' switchboard received 875 calls from people asking what they should do to keep safe. At 9:00 P.M. that night, a woman walked into a New York police station with her two children saying she was ready to leave the city. Several Harlem residents rushed into police stations saying they were packed and

ready to evacuate. Many people had called police stations asking what they should do to avoid the poison hydrogen gas that the aliens were releasing on Earth. Instances like these were reported in several police stations across New York and New Jersey, and reaching as far as the west coast of the United States. Some of these people believed that the United States was actually being invaded by Germans, not Martians.

After learning it was a hoax, many people tried suing CBS for mental pain and suffering, but all of these suits were dismissed. The only plaintiff who won his lawsuit was a man who was suing for the money it cost to buy a new pair of men's shoes; he had spent his shoe money in an attempt to escape the Martians. Upon Welles's insistence, he was reimbursed.

### Subsequent Broadcasts

Decades later, similar broadcasts incited more panic. In 1949, Leonardo Paez produced a *War of the Worlds* broadcast that was translated, adapted, and aired on Radio Quito, a radio station in Quito, Ecuador. In this version, the Martians landed in Ecuador instead of New Jersey. To add to the realism, Paez had articles published in the local newspaper describing strange sightings in the sky above Quito. These articles were printed for a few days prior to the broadcast. No information had been released to the public or government notifying them that the broadcast was a work of fiction.

During the broadcast, mass panic ensued. People were filling Catholic churches for safety and absolution. Anecdotal reports stated that men were even confessing to adultery in front of their wives, attempting to gain forgiveness from God before they died. In addition, the Ecuadorian military assembled in order to battle the Martians. Once the broadcast had ended and the people were notified that it was a hoax, a mob of people stormed the radio station in a rage. After breaking windows and smashing printing presses, the angry mob set fire to the radio station, killing six people. Although Paez survived, his girlfriend and nephew were killed. Paez moved to Venezuela immediately after the incident.

Another broadcast of *War of the Worlds* was aired in 1968 on WKBW radio station in Buffalo, New York. This version had been updated

The August 1927 cover of *Amazing Stories* depicts H. G. Wells's *The War of the Worlds*, a science fiction novel later made into a 1938 radio broadcast directed by Orson Welles. The show, delivered in realistic fashion via intermittent "news" broadcasts, fooled many people into a state of panic.

to fit its time, using disco music and discussing “announcements” from the National Aeronautics and Space Administration (NASA) regarding activity from Mars. Buffalo police received over 4,000 phone calls that night from citizens concerned about the Martian invasion. In addition, the Canadian National Guard released soldiers to the Peace Bridge, Rainbow Bridge, and Queenston Bridge to prevent the Martians from invading Canada.

The *War of the Worlds* broadcasts are prime examples of how deception can be used to create realistic entertainment. However, when the deception is not made abundantly clear, some people may miss the message and thus not realize they are being deceived. In the case of the Ecuadorian panic, the producers were purposefully deceptive—keeping the details of the broadcast’s falsehood to themselves as a means of playing a hoax on the Ecuadorian people. As one can see, the aftermath was horrendous.

a mechanic, mill worker, farmer, and jack-of-all-trades who headed westward with his family from their first home near Rochester, New York, in the 1830s. This hardscrabble life of travel into and across the western frontier instilled in Ward both a love of nature and a competitive spirit toward those of privilege. Ward made up for his lack of access to a formal education by reading whatever he could get his hands on, prodded by his mother, Silence, who taught him from a very early age that “knowledge is power.”

By the time he was a young man, Ward had developed such distaste for slavery that he joined the Union Army in 1862. A year later Ward’s regiment fought in the Battle of Chancellorsville, where he was seriously wounded and taken hostage for 10 days before being rescued. After a period of convalescence, Ward was appointed to a clerkship in the U.S. Treasury Department and thereafter remained in employment in the Washington, D. C. area, including a long career at the U.S. Geological Survey as a botanist and paleontologist, until he accepted a teaching position in the Sociology Department at Brown University in 1906.

Ward’s natural science background informed his sociology, beginning with his first book, *Dynamic Sociology*, published in 1883, and on through to his final book, *Applied Sociology*, published in 1906. It was in *Dynamic Sociology* that Ward presented his theory of the social forces, and among the so-called preservative forces was the law of acquisition. This law incorporates both biology and sociology seamlessly, to the extent that the lower animals struggle to survive in a physical environment through the acquisition of food and other physical necessities, while human beings in advanced stages of development engage in economic activities to acquire valued resources.

### Principle of Deception

A major principle subsumed under this law of acquisition was the principle of deception. According to Ward, deception is the normal form of intellectual action, for it is through deception that human beings obtain everything. The lower animals, of course, engage in deception as well—for example, a mother bird feigning injury to lure a would-be predator away from the nest—yet with the upgrading of the intellect among humans, deception is upgraded as well, even to an art form.

## Ward, Lester F.

Lester F. Ward, a sociologist who developed a principle of deception, was born in Joliet, Illinois, on July 18, 1841. His father, Justus Ward, was

Ward argued that the method of art is artifice, and machines are machinations. Invention is deception to the extent that the forces of nature are ensnared and circumvented. This reflects Ward's argument of the advantages of the artificial over the natural, even as deception springs from the biological in its most rudimentary forms.

The high refinement of deception among humans reflects its evolutionary advantages: early humans who were most keenly deceptive survived and passed on their genes to later generations. Ward also was one of the first scholars—sociological or otherwise—to point out that deception is a fundamental principle which (c.1883) philosophers and political economists had failed to adequately address or conceptualize.

A decade later, in his book *Psychic Factors of Civilization* (1893), Ward had more to say concerning his principle of deception, and here he developed a rule: the greater the deception, the greater the success. For Ward, human society is honeycombed with deception. In the social state, there are many levels and forms of deception, each working in such a way as to secure advantages for the agent at the expense of others. For example, in societies that emphasize the amassing of personal wealth, persons will make displays of such markers of social standing to make others believe they have all they desire, even if they have little or nothing. This idea was the forerunner of Thorstein Veblen's "conspicuous consumption," which Ward originally called "conspicuous puffery."

### Creating a "Sociocracy"

Ward was sanguine about the growing importance of sham, artifice, quackery, imposture, humbug, and jugglery in modern society. He noted that since the beginning of civilized society there has been an effort to regulate muscle power, but now, in order to stem the tide of moral decadence welling up in the modern world, there should also be serious consideration given to regulating brain power. The great panacea, according to Ward, would be the provision of universal education so that all would become knowledgeable about the workings of the social and physical worlds, including, of course, knowledge of that most important principle, the principle of deception.

This would also have the benefit of shifting emphasis from individual intellect—through which

a few savvy operators are able to work the system for the enhancement of self—toward the "social intellect." By maximizing societal knowledge for all, the intellectual faculty could attain its highest purpose, namely, the realization of a "sociocracy" characterized by "attractive legislation," which is the proper end of applied sociology.

Ward asked, "How can society escape this last conquest of power by the egoistic intellect?" The "organized cunning" of charlatans, unscrupulous financiers and industrialists, and others seeking to use their brain power to secure advantages for themselves at the expense of others can be countered only by unleashing the power of society in and for itself. Society should gain consciousness and the indomitable will similar to those of individuals who successfully pursue their interests. A sociocracy fully realized would have individuals use their brain power for the benefit of society, and as all share in the fund of knowledge, all will contribute toward the realization of that end. This would not be a Marxist revolution, however, but a slow, steady, and incremental improvement of society by society.

## Washington, George

George Washington is remembered in American history for his acts of nobility. Much like Cincinnatus, who left his plow to serve his fellow man in battle before returning back to his previous life, Washington exemplified the noble qualities of leadership and direction in the American populace during an era where any lapses in judgment could have led to long-lasting ramifications for the young country. Washington's nobility, according to legend, has a biological root, given the infamous tale of his admission of guilt for cutting down his father's prized cherry tree with a hatchet as a young boy. The story recalls Washington stating: "I cannot tell a lie."

From this beginning, Washington proved to be an admired leader. At first, his prowess spread as a military leader, and he is the individual most often attributed with playing a key role in the success of the Revolutionary War. Despite fears of a new monarch forming, the American public thought so highly of Washington that it elected him the first president of the United States of America. Americans entrusted him with power and never set term limits. True to his character, Washington decided that two terms was the appropriate length for one individual to spend as head executive of the country (an unwritten expectation that was followed until Franklin Roosevelt's time as president during the Great Depression). On his way out of office, Washington warned his countrymen about the dangers of political parties and their potentially corrupting influence on the affairs of the nation.

### Recognition of the Value of Deception

Washington's noble nature did not, however, mean that he did not understand the value of utilizing deceit for strategic reasons and advantage against enemies. As commander of the Revolutionary Army, Washington employed a network of spies and informants to assure that the United States remained a step ahead of the British at every turn. Washington's system of deception included planting false information, denying important pieces of information, and causing an overwhelming sense of confusion. While the soldiers spent a terrifying winter in Valley Forge, Pennsylvania, Washington was concerned with keeping the British away

because he was understaffed and unprepared for prolonged fighting. Washington wrote a series of reports that convinced British General William Howe that Valley Forge was fortified by strong numbers, preventing what would have been a horrible defeat.

Further, in his daily operating plans, Washington was able to mask actual plans and movements by using feints and ploys. When he suggested different potential attack targets, he succeeded in throwing the British off track. Deception played a significant role in the conclusion of the Revolutionary War. Washington made strong assertions that he was diverting all attention toward New York (Staten Island specifically), fully aware that Howe and the British would be listening. Then, he chose to instead head to Yorktown, producing a dramatic victory that started the process of concluding years of battle. To protect his country, even Washington—the most noble and honest of men—was willing to partake in some degree of lying.

Unlike other former presidents, it is difficult to find examples of personal acts of deceit executed by Washington. Many questioned Washington's religious beliefs during his lifetime. Unwilling to speak much about the topic, Washington faced serious questions about whether he believed in God and how his faith (or lack thereof) could impact the development of a largely Christian nation. While the majority of the colonists were members of a Christian denomination (e.g., Puritan, Congregationalist, or Anglican), including Washington's wife and family, the majority of those who rose to elite leadership positions, including the Founding Fathers, were Deists, which did not mix well with Christianity. Even though both religions contain common elements of morality, and they agree for the most part on what constitutes good deeds and proper behavior, the fundamental doctrines concerning which God they worship differs greatly and are incompatible. While scholars today still question Washington's theological beliefs, few have made any progress in proving that he ever concealed his true feelings.

What the case of Washington raises in terms of analyzing lying and deception is how individuals can bend their individual moral codes when called to do so by some higher order. Given the folklore surrounding Washington and the cherry

tree, it is surprising that he successfully executed an entire military offensive built around the idea of lying. Yet, Washington's nobility and honor pushed him to stand for the colonists in their effort to escape what was largely viewed as a demanding, undemocratic force from the Crown. Washington had a moral compass that permitted him to use lies and deceit only when necessary to overcome situations in which others were attempting to violate basic human rights. His decisions to lie were made for the betterment of all, not in self-interest.

## Watergate

Few political scandals of the modern age have rivaled the complexity and, to some extent, the theatricality of those events that have collectively become known as simply "Watergate." In fact, so far-reaching were the consequences of both the initial events and their protracted cover-up that the scandal effectively became the model by which future political and public relations catastrophes were to be defined—not only in America, but also globally. The now common trend of branding a well-publicized cover-up with the seemingly requisite "gate" suffix speaks to the apparent timelessness of the Watergate scandal and how it remains seared into the collective memory, retaining the ability even decades later to connect all

acts of political or public disgrace with Watergate as their common progenitor.

While history has largely focused on the political circumstances of Watergate and its legal and legislative aftermaths, the events that led to the historically unprecedented resignation of President Richard Nixon in August 1974 remain a matter of interdisciplinary interest with respect to the group dynamics of deception and collusion among both elected and appointed officials. In most cases involving criminal acts of deception, the office held by a perpetrator is often considered an aggravating factor at sentencing, especially with respect to breaches of the public trust. Watergate is a remarkable exception, however, in terms of public trust apparently being a mitigating rather than aggravating circumstance, in turn raising questions about the psychopathology of group lying and condoning of antisocial behavior by senior elected officials.

Another reason for the ongoing intrigue surrounding the Watergate scandal is the apparent lack of a concrete motive for the crimes that set the president's downfall in motion and ruined countless careers. The scandal also lacked what might be described as a central or prevailing incentive when considering how quickly it seems to have lured in so many conspirators of such differing backgrounds, many of whom had little to gain during the plotting, commission, and eventual unraveling of the convoluted affair.

#### Burglarizing Democratic Headquarters

Having punctuated an era that remains defined by allegations of clandestine political pacts and far-reaching deceptions and conspiracies, Watergate essentially began as an unexceptional commercial burglary at the Democratic National Committee (DNC) headquarters located in the Watergate office complex in Washington, D.C., on the Memorial Day weekend in 1972. The initial burglary, as with the second attempt in June 1972, was unquestionably an intelligence-gathering mission either ordered or condoned by senior Republican Party principals, including President Nixon, yet the precise nature of the information being sought remains unclear. Some involved in the burglary's planning and commission have cited the official objective as having been the identification and collection of evidence confirming

Members of the Senate Select Committee on Presidential Campaign Activities consult during a hearing on Watergate in 1973. From left: Tennessee Senator Howard Baker, North Carolina Senator Sam Ervin (chair), chief counsel Sam Dash, and minority counsel Arthur Miller (rear). The 435 members of the 93rd Congress (right) were charged with considering the impeachment of President Richard Nixon in 1974, including Texas Congresswoman Barbara C. Jordan (center), who delivered an impassioned rationale for impeachment.

that the Cuban government was providing the DNC with covert funding; others have speculated that it might have been as simple as an overzealous attempt to gather dirt on senior DNC officials through the installation of illegal wiretaps and pilferage of sensitive documents, but with no specific endgame.

What is clear is that both burglaries were carried out by a cabal of undercover operatives, security advisors, and experts in espionage that had been handpicked by Nixon to serve as the White House Special Investigations Unit beginning in July 1971. This group, colloquially referred to as the White House “plumbers,” had the principal mandate—as their unofficial moniker suggested—of locating and fixing leaks, specifically, leaks relating to classified or sensitive information by White House staff and Republican Party members to the press. Representing an array of relevant skill sets and backgrounds, the plumbers’ ranks included not only garden-variety anticommunist politicians, but also former Central Intelligence Agency (CIA) operatives and Federal Bureau of Investigation (FBI) field agents, including chief organizers and unit commanders E. Howard Hunt and G. Gordon Liddy.

While ostensibly formed to “investigate” information security breaches, the White House

Plumbers quickly progressed to becoming break-and-enter artists in earnest. Their first target was the Los Angeles clinic of a psychiatrist treating Daniel Ellsberg, a Vietnam War policy critic and disillusioned military analyst, in August 1971, just a month after their official formation. Following the failure of that operation, the Memorial Day burglary at the DNC offices was similarly deemed an operational failure in terms of the information gathered—or rather not gathered. The plumbers therefore returned on June 17, 1972, to gather further intelligence, only to be thwarted by a Watergate night watchman and have five of its members arrested on site by police.

### The Scandal Exposed

Following the detection and swift arrest of the reputedly stealthy burglars, simultaneous investigations by the FBI and the press—mainly maverick reporters representing the *Washington Post*, the *New York Times*, and *Time* magazine—soon exposed the office break-ins as being camouflaged cases of domestic espionage, effectively connecting the dots between the arrests made at the Watergate complex, the creation of the Special Investigations Unit, and a cache of hush money leading back to Nixon’s administration. After following the evidence up the food chain of the

Republican Party and Nixon's inner circle, when indictments were finally handed down in March 1974, the notoriety of the so-called Watergate Seven as the principal fall guys of the scandal tended to eclipse any attention paid to the other 62 officials indicated, including the original burglars. The selective naming of these usual suspects was in part because—unlike Hunt, Liddy, and the other White House plumbers convicted of carrying out the original breaks-ins—the Watergate Seven seemed to represent both political malfeasance and public deception at their highest, and thus, most publicly condemnable levels.

Forty-eight conspirators were ultimately convicted of various crimes. The conviction of U.S. Attorney General John Mitchell for perjury, as well as the convictions of a number of once-prominent lawyers serving as counsel to Nixon for crimes ranging from perjury and conspiracy to obstruction of justice, was perhaps the most injurious to not only the executive office of the president but also the White House and the democratic process as binary symbols of honesty and integrity in a more general sense. The fact that a number of the Watergate Seven were also lawyers once in good standing introduced an additional dimension to the scandal that brought the ethics surrounding the practice of law into question and the administration of American justice at all levels into disrepute. If the attorney general and other officers of the court at its highest levels were susceptible to political influence and lying under oath, many were rightfully led to question what such revelations said about those practicing law and running the courts at lower levels all across America.

The additional and symbolic arraignment of Nixon in private by the grand jury as an eighth but unindicted conspirator transcended the scrutiny faced by lawyers across the country and ultimately proved a decisive blow not only to the Republican Party but also to the White House as a symbol, undermining months of calculated spin doctoring in an attempt to diffuse the responsibility of the president and any knowledge he might have had of the burglaries and wiretaps. The grand jury's backroom admonishment also seemed to foreshadow the much more public death knell for Nixon's presidency that came just a few months later.

For instance, the sudden emergence of audio recordings dating to June 1972—first made available on August 5, 1974—depicted Nixon spitballing with his chief of staff, H. R. “Bob” Haldeman, about how to divert and mislead FBI investigators working the Watergate case and how to effectively distance himself from the escalating scandal, thereby confirming his having at the very least direct knowledge of the burglaries from the outset. Four days later, on August 9, 1974, amid impeachment proceedings in Congress, Nixon resigned from office. After ceding the presidency to Vice President Gerald Ford, within a matter of months Nixon was pardoned by the newly appointed president for any crimes he may or may not have committed while in office, largely if not exclusively in relation to the Watergate affair.

### Aftermath of the Scandal

While Washington officials and the Executive Office of the President were by 1974 no stranger to public hearings and federal investigations of varying severity and legitimacy, Watergate was a proverbial game changer in terms of the criminal culpability of senior politicians up to and including the president, and it would set the stage for prosecuting acts of perjury committed by officials prepared to lie under oath. The 13 indictments handed down following the Iran-Contra scandal just over a decade later—one of the first to invoke the requisite “gate” suffix in the wake of this scandal and often known as “Irangate”—was perhaps the most significant example to occur on the heels of Watergate. Not unlike its predecessor, Iran-Contra was defined by minimal, perfunctory sentences, and in most cases full presidential pardons issued immediately thereafter. Such gestures of judicial glad-handing suggest that offenses such as perjury that encompass lying, deception, and breaches of the public trust are not only deemed permissible but are also considered necessary transgressions that are to be tolerated once lying reaches certain “official” levels at the upper echelon of governmental power.

The prosecution of the Watergate Seven and their paltry sentences, if any, additionally points to a chasm between the expectations of truthfulness among the general public versus greatly diminished expectations among political officials; it to some extent also quantifies deception and collusion as

occupational necessities of political life. The lack of any tenable repercussions with respect to not only the original criminal acts in the Watergate affair but also the unrelenting lying under oath that followed suggests that holding public office, even by association, in effect socializes one to lie, deceive, and mislead as a matter of course.

Moreover, the timing of the Watergate prosecutions is remarkable in terms of the other priorities of American justice in the 1970s with respect to corruption and collusion. The rationale behind the Watergate sentences seems to stand in stark contrast to the prosecutions and litigations initiated under the Racketeer Influenced and Corrupt Organizations (RICO) Act, which went into effect in 1970, just four years prior to the indictment of the Watergate Seven and Nixon's resignation.

The prosecution of the Watergate Seven approximated the public dismantling of an organized crime syndicate under the guise of the newly minted RICO legislation, with roles and ranks in the criminal hierarchy being identified, marching orders fleshed out, and the intensity of the prosecution—and media attention—being commensurate with the prominence of an accused within the group. Unlike in the case of most organized crime groups prosecuted under the contemporaneous RICO legislation, however, the Watergate Seven lacked a common ideology or code that allowed them to close ranks and maintain any semblance of solidarity during the investigation, indictment, arraignment, and trial. In fact, one of Watergate's enduring contributions to the study of deceit is the demonstration that organized crime and criminal organizations are not necessarily one and the same and that collective lying and perjury by a group is not always indicative of a common end.

As the main players in the Watergate affair ultimately came to be part of a coalesced criminal syndicate largely by default, most were ultimately acting out of their own opportunistic interests from the outset—motives that ultimately came to the fore once names were named, and it became a matter of every man for himself. In the end it would seem that political affiliation is not the most effective of mortars in holding together an already dubious and unconvincing story over the long term.

## White House Press Secretaries

An entire genre of literature has developed consisting of former White House press secretaries penning autobiographies containing apologies or shifting blame for their deceptions of the American public. The standard refrain, as stated by Herbert Hoover's press secretary in his diary, is that the job limits its practitioner from ever being "able to tell the whole truth." Press Secretary Scott McClellan defended George W. Bush's Iraq War from the lectern, only to later write a book about the "culture of deception" he helped perpetuate in the White House.

The press secretary presents interpersonal contexts in which deceptiveness can be explicit, routine, and expected. The first president to have someone serve with the title *spokesman* was Calvin Coolidge. It was a deceptive ploy: the "spokesman" was Coolidge himself, but reporters were too scared of the president to report this. A variation of Coolidge's tactic reemerged in the

1990s. Bill Clinton's second press secretary, Mike McCurry, invented the term *psych-background* for the president giving background information to reporters, in which Clinton would answer reporters' questions aboard Air Force One, but reporters were only allowed to attribute the quotations to an unnamed "highest authority."

During the administration of Franklin Delano Roosevelt (FDR), Stephen Early became the first White House staff member whose sole responsibilities were overseeing daily press briefings and speaking for the president. Early's handling of his job made him the first official White House press secretary both in terms of his title and duties.

Before FDR, presidents considered it beneath them to hire media handlers in the White House. However, some White House staff members acted as media liaisons in addition to performing other duties. These White House staffers were not always held in high regard. One of Andrew Jackson's critics in Congress referred to Jackson's media liaison as a "lying machine." Hoover's press secretary was considered a "cordon of duplicity" by journalists.

### Press Secretaries' Deception

A press secretary's job often requires him or her to deceive reporters. For example, after Gerald Ford's first press secretary resigned abruptly, Ron Nessen of NBC News was interviewed at the White House for the opening. When reporters asked him if he was under consideration for the job, he lied and replied, "Not that I know of." Neesen, however, was appointed Ford's press secretary, and he spent his first several days at the podium apologizing to journalists for the lie.

In 1980, the *Los Angeles Times* asked Jimmy Carter's press secretary, Jody Powell, if the White House was launching a mission to rescue hostages in Iran. Powell said no, even though less than a month earlier he had attended a meeting about a rescue plan. Later he called the reporters to confess: "I just lied to you."

Ronald Reagan's acting press secretary, Larry Speakes, distributed quotations to reporters, claiming they were excerpts from a closed-door meeting the president held with Soviet leader Mikhail Gorbachev. Reporters printed them, not knowing that Speakes had invented the quotations himself, a feat he would disclose boastfully in his

published memoirs. In a White House briefing on October 12, 1982, Speakes admitted that his role was "to stage the news," and he proudly displayed this quotation on his desk. George H. W. Bush's press secretary, Marlin Fitzwater, was accused of lying about the White House's foreknowledge of a coup in Panama.

History probably considers Ron Ziegler to be the most deceptive press secretary. After all, he spent more than 10 months parroting the Nixon administration's evolving comments on Watergate. Ziegler first termed the scandal a "third-rate burglary" before shifting his comments and saying all his previous quotations were "inoperative." At briefings, reporters called him a liar to his face. However, in the 33 times that Ziegler testified before congressional hearings on Watergate, no evidence linked him to the cover-up. Two years after he left the job, Ziegler made a quasi-confession, saying that press secretaries lie because they repeat what their superiors tell them.

### Deceptive Health Communications

Communication about the president's health is a frequent theme of press secretary deceptions. The first recorded account of a White House spokesman lying to reporters at a press briefing was in 1893, when President Grover Cleveland's secretary of war told inquiring reporters that their speculations about the president having surgery were wrong. The nation was in a recession, and Cleveland feared his economic plan would be doomed if the public knew his doctor thought he could have cancer. During William McKinley's second term, his health plummeted. He had eye trouble, was bed-ridden with the flu, and near death from pneumonia. Yet his secretary tamped down media speculation, saying that reports of the president being ill were "foolish stories."

William Howard Taft's press spokesman became sickened from stress and fatigue, went to Rome to rest, and lied to reporters that his trip was to meet with the pope. When Woodrow Wilson became gravely ill of syphilis, his spokesman issued press statements that the president was recovering from fatigue. For the entirety of his service to FDR, Early tried to hide the president's health travails from the press. Even after FDR died, Early released a statement that "the president was given a thorough examination by seven or eight physicians" and "he

was pronounced organically sound in every way.” Dwight Eisenhower was hospitalized with a heart attack, but his press operation initially told reporters he had an upset stomach.

On the other side of the coin, when John F. Kennedy was holding secret meetings dealing with the Soviet Union and the Cuban Missile Crisis, his press secretary Pierre Salinger told reporters that the president’s schedule changes and lack of public appearances were due to a cold. He even released the president’s symptoms and temperature. Salinger also used the same cold excuse to explain Vice President Lyndon Johnson’s impromptu flight from Hawai‘i to the White House at the same time.

### Press Secretaries and Political Spin

Rather than calling out press secretaries’ tactics as lies perpetrated upon the Fourth Estate, academics often speak of the message being “mediated” or “framed.” Practitioners admit that their methods are “spin.” Spin ranges from euphemisms that emphasize the positive to falsehoods with dire consequences. Stephen Frantzich, a political science professor at the U.S. Naval Academy, conceptualized a press briefing exercise for instructors in order to help their students decipher the truth from bias and misinformation at the press secretary’s daily briefing. According to Frantzich, the daily briefing is a battle with reporters attempting to get the press secretary to divulge more than he or she wishes. Studies such as these help students examine ethical issues concerning the press secretary’s work.

From a government policy and legal standpoint, the press secretary, a federal employee, is put in a position of advocating partisan stances and campaign platforms. Also, most press secretaries come from journalism backgrounds. The fact that presidents will most likely pick their press secretary from an applicant pool whose job is to cover the president objectively raises concerns about source-reporter relations. After the job is over, the press secretary likely will return to journalism and pen an apologia for his or her White House job.

## White Lies

A white lie is a form of deceit that is generally socially acceptable because it holds the potential to prevent or minimize another person’s emotional pain. Individuals report telling white lies with greater frequency than serious lies; however, they remember the white lies less than the serious lies.

### Social and Emotional Benefits

Deception, especially in the form of a white lie, probably has emotional benefits for both the listener and the liar. One possible benefit could be that listeners might not always want to hear the truth for adaptive reasons (for example, it might hurt one’s feelings to learn another person’s true views). Second, contrary to most forms of deception, white lies are less likely to elicit negative emotions from the liar because the individual who tells the white lie has less fear of being caught or feeling guilty for protecting another person’s feelings.

White lies help maintain social relationships but also aid in maintaining a sense of privacy. For example, an individual may not want to review his or her true condition and thus claims to be fine even when he or she is not. Another form of white lie is making excuses to protect one’s privacy or to avoid hurting another person’s

feelings. According to social etiquette, in some circumstances telling the truth is impolite. For instance, a white lie may be encouraged in the place of expressing true sentiments after having received a gift. In fact, individuals who continuously express all of their negative impressions and feelings and never tell any white lies may face difficulty fully integrating themselves into social settings and groups.

### **Self-Centered Lies and Other-Oriented Lies**

Distinctions have been made between self-centered lies (that is, ones that benefit the liar) and other-oriented lies (that is, ones that benefit the listener). Other-oriented lies are similar in nature, if not the same, as white lies. Diary studies, designed to record participants' everyday lying behaviors, have revealed that individuals engage in other-oriented lies to protect others from embarrassment, to avoid hurting their feelings, to protect a sense of privacy, to improve another's image, or to regulate another's emotions. Although the primary goal of other-oriented lies, or white lies, is to protect another individual, white lies also seem to help safeguard the liar's well-being by helping him or her avoid arguments and maintain strong relationships. Individuals report telling more self-centered lies to strangers and more other-oriented lies to their friends.

### **Gender Differences in White Versus Black Lies**

Two other types of white lies have been proposed: Altruistic white lies may harm the liar but are beneficial to another individual; whereas a *pareto* white lies lead to benefits for both the liar and another individual. Women are more likely to tell the former type of white lie than are men, who are more likely to tell the latter type of white lie. Black lies, in contrast, are lies that benefit the liar at the expense of another individual and can be divided into selfish black lies and spiteful black lies. Men are more likely to tell selfish black lies than women are.

### **White Lies in Childhood**

By age 3, children have developed the skills needed to control their nonverbal display rules, such as hiding disappointment from others. As early as age 4, children prefer white lies to nonwhite lies

and believe them to be an appropriate method for protecting the feelings of another individual. As children begin preschool and developing their higher order cognitive functions, they tell more white lies and become more equipped at maintaining their falsehoods. In lab settings, when parents give their child prosocial rationales for telling white lies, children are more likely to tell a white lie than are children who are not reminded of prosocial rationales. However, many children will engage in white lie telling in lab settings without being prompted, and older children are more likely than their younger counterparts to provide detailed rationales for their lies. Although children know that lying is considered to be wrong, they seem to understand at a young age that white lies can help spare another's feelings and that it is often considered a good thing to do.

### **White Lies in Adulthood**

Adults evaluate lies that benefit another person as less deplorable than lies that are told for personal reasons, such as avoiding harm to oneself or for personal gain. Thus, the underlying motivations of the lie are paramount in determining the severity and morality of the lie. Similarly, according to the Cultural Model of Lying, the motivations of the lie and its context determine the type of lie it is. Because the motivation behind a white lie is typically to protect another person's feelings, it is usually not considered immoral to tell a white lie. Even in the context of intimate relationships, adults evaluate white lies as the least immoral form of deception compared to other lies.

Individuals often experience two opposing thoughts when considering telling a white lie: the social rule that one should always be polite and the moral rule that one should be honest. The desire to be polite often outweighs the potential costs of being completely honest in intimate relationships. For adults, maintaining a harmonious relationship and protecting the feelings of one's partner or friend can often be preferable to being completely moral and truthful. Interestingly, white lies, unlike other types of deception, do not appear to have detrimental effects on relationship satisfaction. In many situations, adults prefer to hear a white lie from their partner than a blatant truth that will make them feel bad about themselves.

Individuals have a wide variety of reasons for telling a white lie, but predominately, white lies are told to protect another person from harm and are thus considered to be the least immoral form of deception. In fact, in many situations, an individual would likely choose to tell a white lie over the truth if only to protect another person's feelings.

convicted. Eyewitness research indicates that false witness evidence can result from errors in memory, suggestive investigation procedures, malingering, and inability to distinguish truth and lies. However, because of complexities in the charging and recording process, as well as difficulties in establishing the ground truth, the extent of witness error and deception within the criminal justice system is unknown. Whereas eyewitness evidence is overly relied upon by jurors, alibi witness evidence is generally presumed to be deceptive by jurors.

Relatively little research attention has focused upon deliberately deceptive witnesses, with a general focus instead upon eyewitness inaccuracy as an unintentional process. Memory is not perfect, with the potential for errors to occur in the information taken in at the time of an event, the storage of that information, and the later recall. Encoding can be affected by inattention to the event, poor visibility, and stress at the time of witnessing the event caused, for example, by violence or the presence of a weapon. If the crime is not thought about for a long period of time the details can be lost in a process of decay. Finally, interference at the time when the memory is retrieved can cause distortions and errors.

Much research has examined how suggestive police questioning, positive feedback, and repeated exposure to line-up procedures can cause eyewitnesses to have a vastly distorted memory of a crime despite honest intentions to recall the event accurately. The work of Elizabeth Loftus and John Palmer in particular highlighted that the terminology used in questioning could cause participants to overestimate the speed a car was travelling prior to an accident, falsely recall broken glass being present, and remember incorrect information on road signs.

### Witnesses' Motivations to Deceive

The focus upon witness error instead of deception may result from the fact that, generally speaking, witnesses have less motivation to lie than suspects. Suspects have nothing to lose by lying, as successful deception may help them evade conviction, and failed lies are unlikely to attract charges in addition to their index offense charges. In contrast to this, witnesses who would otherwise not be at risk of prosecution stand only to lose should

## Witness, False Testimony of

The false testimony of witnesses has the potential to allow guilty suspects to evade conviction and cause innocent individuals to be falsely

*Bobby Seale listens to testimony during the Black Panther Party trial in New Haven, Connecticut, in 1971, in which he was questioned about his involvement in the inside-job torture and murder of a Black Panther Party member. The case was a political hotbed that intensified hostilities between organized political dissent and the government. Seale had a strong motivation to provide false testimony, and his involvement was never proven.*

their lies be discovered. This lesser motivation to lie, and the consequent rarity of witness deception, is the likely reason that most of the deception research has examined detection of suspects rather than witness deception. However, there are two broad reasons why eyewitnesses may provide deliberately deceptive accounts: malingering and fear of offender retribution.

Malingering refers to the fabrication of information for some form of personal gain, whether that be financial, the desire to hurt someone, or the heightened levels of attention experienced as a result of the false claim. In extreme cases this can lead to the false accusations of a crime occurring. There are many documented cases of false allegations of rape, sexual assault, physical assault, and stalking in particular. These accounts can often be very convincing, although there is a suggestion that deceptive witnesses assert

more frequently that they are telling the truth. Moreover, comparisons of genuine accounts of rape with simulated accounts from nonvictims, show that false accounts tend to contain less unusual sexual behaviors and more references to verbal and physical violence. It is generally agreed that malingering is relatively rare and that a more common cause of witness deception is intimidation.

Fear of offender retribution seems to be valid, with approximately 50 percent of vulnerable witnesses reporting intimidation from the defendant and the defendant's family prior to trial. The effect of in-court witness intimidation can be overcome through safeguarding measures, such as the use of closed-circuit television (CCTV) links and screens to hide the witness. However, intimidated witnesses may be more prone to deception in order to prevent the case reaching court. Research investigating deception in fearful witnesses has employed an experimental paradigm in which participant eyewitness to a mock crime are instructed to either attempt to correctly identify the offender (truthful), or to imagine that their family would be harmed should they fail to protect the offender (deceptive). This research demonstrates that witnesses tended to protect the offender by overestimating their height, age, and weight in descriptions given to the police. Interestingly, deceptive witnesses tend to state that the offender is not present in the suspect line-up and reach this decision much faster than truthful participants.

As jurors do not perceive impartial eyewitnesses as deliberately deceptive, they presume they must be accurate. This means that jurors place a disproportionately large amount of faith in the accuracy of eyewitnesses, potentially to the detriment of the case. Moreover, when evaluating eyewitness evidence jurors often rely on factors that are not reliable indicators of accuracy. For example, although jurors perceive witness confidence as indicative of accuracy, research shows that there is actually no correlation between confidence and accuracy. However, when participants are specifically instructed to detect which of several witness accounts are genuine and which are deceptive, deception detection abilities show the same truth bias found in studies examining suspect deception detection.

### Child and Elderly Adult Witnesses

The evidence of child witnesses is often treated with considerable suspicion. That is not to say that children are thought to frequently maliciously fabricate information; rather their incomplete cognitive development is seen as preventing them from differentiating between truths and lies. Several countries (such as the United States and Australia) actually insist upon an assessment of truth-lie understanding for child witnesses in an attempt to ascertain the validity of their in-court evidence. However, other countries only ask children to promise to tell the truth (Canada), or do not assess children's understanding of truth and lies at all (Scotland). As children have a tendency to agree to information presented to them and a desire to please adults, it is even more important that police avoid suggestive questioning with child witnesses than with adult witnesses.

It is intended that pointing to body parts on an anatomically detailed (AD) doll allows linguistic and developmental barriers to effective communication to be overcome when children are the victims of or witnesses to a sexual offense. However, more recently the use of AD dolls has proved controversial, with concern that the everyday use of dolls as a plaything may promote fantasy play rather than truth. In general, research into the use of AD dolls suggests that although they increase the quantity of information elicited, this is likely to be due to careful accompanying questioning, rather than the AD doll itself. Nonetheless, AD dolls may be useful in gathering children's terminology for various body parts when the anatomically correct terms used by adults may be unfamiliar to the child.

In general, their developing moral standards mean children may not appreciate the consequences of their false information and so fail to feel guilty. This means that there are significant barriers to the accuracy of child witness accounts, and accuracy rates at detecting children's deception are comparable to those of adult deception suspects, being at roughly chance levels.

Research into elderly adults' eyewitness accuracy in general and more specifically consideration of their deception is at present limited. It appears that older adults show decreased accuracy compared to younger adults; however, older adults appear to be overconfident in their memory and

identifications. This difference in ability seems to be recognized by jurors and police officers, who rate older adults as less capable of giving accurate information than younger adults. However, both of these groups recognize that older adults are not less honest than younger adults; in fact, they are perceived as more honest. Given the aging population of many developed countries enhancing the likelihood of crime witnesses being elderly, more research on this issue is needed.

### Weak Alibi Witness Evidence

The plethora of research examining suspect deception and eyewitness testimony means it is surprising that research into the second leading cause of false convictions—weak alibi witness evidence—is limited. Mock detectives provided with both eyewitness and alibi witness statements generally do not differ in their ratings of suspect guilt compared to mock detectives that receive only an eyewitness statement.

This shows that alibi evidence carries relatively little weight compared with eyewitness evidence. In fact, real-life cases have shown that the presence of up to 40 defense witnesses can be insufficient to deter jurors from believing the testimony of a single eyewitness. This led to the development of the alibi skepticism hypothesis, the idea that evaluators view alibi evidence with considerable suspicion.

Some mock juror research has found a higher frequency of guilty verdicts when defendants' alibis are corroborated by their family compared to corroboration from a stranger, or having no corroboration. It is suggested that this differential treatment of alibi witnesses is due to a presumption of deception among individuals with an existing relationship to the defendant. This has led the alibi witness research to categorize alibi witnesses as either motivated (that is, a parent, partner, or sibling) or unmotivated (that is, a stranger or colleague) to lie for the defendant. There is some basis for this evaluator skepticism as research utilizing a mock suspect and mock alibi witness paradigm shows that incriminating evidence is concealed less often for a comparative stranger than for a partner, parent, or friend. However, motivated witnesses are not consistently associated with either concealing or revealing implicating information about suspects, showing that there is a

complicated relationship between motivated alibi witnesses and alibi honesty. In fact, it appears that personality and individual differences are important factors in alibi witness deception.

### Conclusion

Witnesses may provide false testimony either deliberately or unintentionally. Unintentionally false accounts may result from poor event encoding and negative influences during memory storage and retrieval. Witnesses for the prosecution are generally thought by jurors to be accurate, with malingering and intimidation receiving relatively little research attention. In fact, with the exception of research into children's abilities to differentiate between truth and lies, the psychological literature generally focuses upon witness errors rather than deliberate deception. Research into alibi witness evidence is almost exclusively focused on deception, showing that there is considerable support for the alibi skepticism hypothesis and the enhanced suspicion directed toward motivated alibi witnesses.

## Wizards of Lie Detection

"Wizards" of lie detection, or "truth wizards," are people with an unusually high rate of accuracy in lie detection. As defined by the Wizards Project, wizards are at least 80 percent accurate in their identification of truths and lies, compared with the 50 percent rate in an average person (the same rate achieved by means of sheer chance, like flipping a coin). Out of 20,000 people tested by the project, only 50 were identified as wizards, indicating that lie detection talent is more sparsely distributed in the population than academic prowess or athletic ability. Initial criticism focused on the possibility that the discovery of such a small number of wizards could indicate sheer coincidence. A Winston Salem State University study, however, while using a smaller sample size (about 250 people), found similar results.

The Wizards Project was organized by psychologists Maureen O'Sullivan and Paul Ekman at the University of California, San Francisco, and was originally called the Diogenes Project, after the Greek philosopher Diogenes. One of the questions raised by the project's study is where lie detection ability comes from: whether it is learned, a side effect of other competencies, an innate talent, or whether there might even be a gene for it. Apart from Secret Service agents, in the initial study, law enforcement professionals and psychologists performed no better than undergraduate volunteers, which suggests that it is not an ability simply developed by working in a field in which lie detection is useful.

Ekman is one of the most widely cited researchers in psychology as a result of his work in the project, especially his study of the way that facial expressions reveal emotion, which are then detected by wizards. He has argued for biological correlates to emotions and emotional responses, a model that has become central to the field of evolutionary psychology and which restored the Darwinian view of emotional expression after a period in which it had fallen out of favor because of the dominance of the anthropological view that specificity of emotional expression was culturally determined. This difference between cultural and biological determination is key to the concept of truth wizards as understood by the project and research based on its findings.

## Universal Emotions

While movies and TV shows will often show a wife telling her husband that she knows he's lying because he always tugs on his beard when he lies, that is a "tell," which depends on the detector's intimate knowledge of the liar and is uniquely characteristic of the liar.

That sort of lie detection is of no real use to law enforcement professionals. Ekman's work instead proposes universal emotions—emotions that are expressed in significantly similar ways throughout the human race, regardless of culture—specifically, universals in the expressions that indicate deceit or distress on the part of the speaker. The existence of biologically determined universals does not mean that the husband might not also tug his beard while lying; it only means that other means of detecting his lie also exist. Some of Ekman's work has focused on showing that these universal expressions are present in tribal cultures that have had no contact with depictions of emotion, that their universality cannot be explained through a mechanism by which those expressions were learned.

Key to Ekman's work on the project is the idea of microexpressions. Microexpressions are facial expressions which occur very briefly, for a fraction of a second. They are involuntary, and because of this, they are most likely to be seen when a subject is consciously trying to restrain his facial expressions or emulate an emotion that he is not feeling. This is especially true in times of great stress. Ekman did not discover microexpressions, which were detailed in the 1960s by E. A. Haggard and K. S. Isaacs in a study of "micro-momentary" facial expressions in psychotherapy sessions. He pioneered in the relevance of microexpressions to lying and lie detection, theorizing that "natural-born liars" exhibit a degree of control over their microexpressions that is lacking in the general population, while truth wizards pick up on these microexpressions, along with other verbal and nonverbal cues, in making their estimation. Although microexpressions are easily observed on film or video, they are difficult to perceive otherwise, and because of their brevity and subtleness, most people do not even notice that they are occurring, especially if the face is in movement anyway because the subject is speaking.

Microexpressions have entered the popular imagination with the television series *Lie To Me* (Fox, 2009–11), to which Ekman served as consultant. *Lie to Me* takes the existence of truth wizards as its premise, with the protagonist, played by Tim Roth, lending his lie detection abilities to law enforcement investigations. Roth's partner, played by *The Practice*'s Kelli Williams, is loosely based on O'Sullivan. Before she passed away in 2010, O'Sullivan was critical of certain aspects of the series, particularly that it oversimplified microexpressions and other behaviors that indicate mood.

Ekman has contributed to work on developing a lie detection software program that detects microexpressions in much the same way that wizards do. His work has also been used to develop the Silent Talker, a lie detector developed at Manchester Metropolitan University in the early 2000s. The Silent Talker uses cameras to observe a subject in order to feed video information to a software program that analyzes nonverbal behavior, including microexpressions, cognitive load, and duping delight. The Wizards Project has led to a small cottage industry of services claiming to train people in lie detection by teaching the methods used by truth wizards. Apart from a handful of legitimate research endeavors like software lie detectors, there is little experimental data on these services, nor reason to trust their efficacy.

## Women

Scholars in various fields have devoted significant attention to understanding the discrepancies in men and women's engagement in social deviance pertaining to lying and deception. Although biological sex is a known factor contributing to the use of deceptive communication, research to date has also demonstrated the relevance of social norms and contexts that shape the influence of both sexes in criminal activities and intimate relationships. Because of different life experiences and levels of self-regulation, women differ from their male counterparts with respect to the types of crime they are choosing to engage in. In the arena of a romantic relationship, both men and women are likely to use deception to attain their means, though in different ways.

Among the human impulses that enhance the ability for survival and shape modern lifestyles, human nature consists of a fair number of selfish drives and urges that often propel one to lie and deceive. Classic works as well as the most recent empirical findings have illuminated the intimate link between biological sex and social deviance. Research, which attempts to understand the discrepancies of deviant behaviors, such as each sex's tendencies for betrayal, cheating, and destructive behaviors, has considered a number of theoretical explanations. Specifically, behavioral distinctions are made to elucidate how females differ from their male counterparts from various perspectives, ranging from the biological aspects to the social domain. Further, cultural stereotypes also call upon the normative standards that women should be evaluated against, as the legacy of moral standards continues to shape contemporary gender ideologies and identity development.

But biological sex is not the only static attribute when it comes to deception; it is also crucial to pinpoint the environmental forces and multiple social contexts influencing the inherent capacities and predispositions of human nature. In general, social norms that encompass the established regulations and behavioral expectations not only provide rules of conduct for men and women but also are essential for society's survival. Moreover, social stigma in supporting the perpetuation of social inequality also has its most profound impact on social marginalization of women who

deceive. But a comprehensive examination of women's experience requires the exploration of their relationships with their male counterparts.

### Women and Crime

In the realm of criminal activity, most social research on adult criminality focuses on the understanding of male behaviors and neglects to consider the impact of gender discrepancies in life experience. Specifically, ample evidence suggests that women, unlike men, are less likely to undergo the same events that propel men to crimes involving lying and deception. Because men and women experience different forms of strain, they are likely to possess different interpretations and conceptualizations of the types of strain they encounter. Hence, men and women's emotional reactions to strain, propensity to react to strain with crime, and respective pathways to crime may differ.

Further, women also face additional problems conditioned by class and race. Minorities represent a disproportionate number of incarcerated women, and these women have depleted economic resources, poor educational attainment, minimal marketable skills, and job experiences. Many women also identify the abuses they experienced as the leading cause of their law-breaking. Their life experiences are likely to be accompanied by emotions such as depression, guilt, fear, and shame, which further decrease their likelihood of committing serious property crimes and violent crimes against others but increase the likelihood of self-destructive and noncriminal offenses motivated by substance abuse and poverty. These crimes are often used to finance their daily activities and meet the needs of others. As such, unlike their male counterparts, who are more likely to be involved in corporate crime, women are more likely to engage in petty thefts.

The functions of self-control and social control have been the primary focuses of men and women's lying and deceptive behaviors and, ultimately, their criminal activities. Differences in both internal and external mechanisms between sexes are strong predictors of the frequency as well as the types of deception in which men and women engage. Empirical research on the self-control theory postulates that individuals with higher self-control are in a better position to regulate their urges and impulses. Without an internalization of

the mechanisms and values that restrain propensity to social deviance, both men and women are equally likely to turn to deception at the expense of others.

Low self-control is associated with impulsivity and short sightedness; individuals with low internal control also have weaker ties that foster strong social control. Existing evidence generally supports the notion that women exhibit greater self-control compared with men in most cultures. The gendered socialization process, in particular, may account for the source of this variation as boys are socialized to be greater risk-takers, whereas girls are taught to be more reserved and conservative. Because of different social expectations of what constitutes appropriate behavior for boys versus girls, parents may be quicker to recognize and punish impulsivity and deviant behaviors exhibited by daughters rather than sons.

Nevertheless, family socialization alone does not insure the acquisition of self-control and conformity to societal norms. Extra familial socialization within schools and community are also strong determinants of self-control and the motivation to deceive. Even though both men and women are generally concerned with how they are being perceived by others in order to be in line with the “good boy” and “good girl” orientation, social institutions and the general public typically place harsher punishment on women who deviate from the social norms when compared with their deviant male counterparts.

### **Deception in Romantic Relationships**

Lying and deception do not necessarily lead to criminal offenses. Many of the same motives that propel deceptive orientation also motivate non-criminal behaviors in everyday lives. Whereas self-control is essential to understanding the sex differences in criminal involvement, the frequency of deception and deception motivations are contingent upon the nature of the opportunities afforded to both sexes, as well as the rational calculation of potential benefits and risks of their deceptive behaviors. Deception is commonly used by both men and women who are seeking potential mates. Because each sex looks for potential partners with the most appealing characteristics, evolutionary and social psychologists contend that to increase the probability of successful mating, both genders

are likely to utilize lies and deception in order to conceal drawbacks and limitations to their real identities and resources. Stated simply, in finding and keeping a mate, women, just like men, are compelled to maximize the positive impressions they make and to display the possession of desirable characteristics or imply that these characteristics will be acquired in the near future.

Differing perceptions of attractive partners for men and women, as well as the need to compete with rivals for attractive partners, makes a certain degree of deception necessary in the mating and courtship process. Although the most sought-after traits are fairly consistent across cultures for both men and women, certain traits are given relative importance based on each sex. For example, women seek emotionally committed and financially stable men, whereas men opt for women with youth and beauty. Essentially, in order to maximize the chances of finding a mate, women are compelled to display the characteristic that is deemed important for men: physical attractiveness. To maximize the possibility of finding an attractive mate, some are reticent to disclose certain types of information to potential partners.

Specifically, a woman's deception can take many forms, ranging from changing her appearance to concealing body parts that are believed to be inadequate. Just as women are likely to deceive men with respect to their actual physical attractiveness, women anticipate that men will be less truthful when disclosing characteristics vital to women, such as financial position and level of dedication to the relationship. Nevertheless, successful mating is most likely when deception is least expected by either gender.

The decision to deceive is connected to perceived payoffs accrued from the deceitful behaviors. Women's deceptive behaviors in mate selection are intimately related to their reproductive experiences. From the evolutionary perspective, women have two dominant interests in men: genes and resources. Women bear increased costs from potential mating “mistakes,” and reap increased reproductive benefits from mating with someone possessing resources essential for their offspring. As a consequence, women are motivated to develop strategies that optimize the chances of obtaining men with superior genes and resources in order to insure the survival of the next generation.

Unlike men, who are generally more interested in multiple partners, women prefer men who are committed to helping raise offspring. Ultimately, the relative scarcity of high-quality genes makes it imperative for women to develop “deceitful” mating strategies in order to secure investment from men, which increases the chances that good genes for her offspring will be passed on.

Importantly, lying and deception do not end with a marriage license; infidelity is pervasive among some married couples, despite the fact that infidelity is socially and culturally frowned upon. With respect to the frequency of infidelity, early studies indicate that men are more likely to engage in infidelity than women. However, more recent studies demonstrate that the gap has narrowed. In other words, when other forms of infidelity (for example, emotional infidelity) are considered, women commit as much infidelity as men.

Many theoretical explanations have been advanced to explain the basis for infidelity. Empirical findings suggest that women may be more likely to be unfaithful to a partner if his genetic quality is low in order to increase the probability of gaining high-quality genes. Although infidelity can be caused by various situational factors, such as the availability of adequate opportunities, these factors alone cannot explain an individual's decision to stray in a committed relationship. Rather, gender differences in the rate of infidelity are also mediated by a person's ability to regulate their impulses and overcome their desires.

Men and women may have different conceptualizations of infidelity. Unlike men, women tend to perceive their affairs as emotional rather than sexual. Likewise, because emotional infidelity increases the chances that male partners will divert attention, time, and resources to a rival, women may become more wary of their partner's emotional infidelity than of their sexual infidelity. Perhaps one of the strongest personality predictors of infidelity is gender differences in regulating the feeling of guilt. Committed women are especially more sensitive to a partner's feelings. Further, unlike women, men experience less guilt following an infidelity, and are more likely to justify their behavior.

Most of the gender studies and findings reveal women's greater tendency to be more empathetic and sensitive about other people's needs

and less likely to use deception to attain their means. Alternatively, because women typically realize the potential damage to their relationship, they are less likely to use deception for fear of jeopardizing their relationship. Finally, personality scholars suggest that females also experience more anxiety when deceiving. With respect to the nature of their deception, men are prone to telling selfish lies, whereas women are more inclined to tell altruistic lies. Regardless of the motivation for infidelity and cheating, women who deceive are more likely to be stigmatized and encounter gender-based double standards.

# World War I

World War I, also known as The Great War, took place between July 1914 and November 1918, and involved a complex web of motives, alliances, and accusations that led to several important forms and instances of deception. Before and during the war, countries involved in the conflict used propaganda to mislead their citizens about the status and reasons for fighting. Aided by new technology, World War I also brought about the creation of deadly weapons that relied on tactics of deception and subterfuge, such as the infamous U-boats. Additional notable examples of deception in the war were the sinking of the *Lusitania* and the Zimmerman Telegram, both of which influenced the United States' decision to enter the war. Further, the U.S. public supported the war because of intentional misinformation both about conditions on the front line and the character of the opposition.

## Alliances and Motivations

Alliances and motivations prior to World War I are important to understand key deceptions that led to the conflict and influenced the manner in which the war was waged. The war began when Archduke Franz Ferdinand, heir to the Austro-Hungarian throne, was assassinated on June 28, 1914, by the Black Hand, a Serbian secret nationalist society. Austria-Hungary blamed the Serbian government for Ferdinand's death and issued an ultimatum demanding the apprehension of the assassins. Austria-Hungary's goal was to undermine Serbian authority in order to incite a reaction that would give Austria-Hungary a reason to declare war. When the Serbian response to the ultimatum was not satisfactory, Austria-Hungary took the opportunity to declare war.

Alliances were formed and declarations were made in rapid succession. Russia declared war on Austria-Hungary in support of Russia's ally, Serbia. Germany joined the conflict using the nation's treaty with Austria-Hungary and Russia's mobilization against Germany as a reason to declare war against Russia. Because of an alliance with Russia, France found itself pitted against Germany and, by extension, Austria-Hungary. Germany invaded Belgium en route to Paris, bringing Great Britain and its colonies into the war based

on a long-standing agreement to defend Belgium. All of this occurred within two months of Austria-Hungary's initial declaration of war against Serbia. Austria-Hungary's ultimatum had been quickly converted from a limited war to a worldwide engagement.

The quick escalation of the war was caused not only by the tangle of alliances but also by underlying, and less public, nationalistic motives. Otto von Bismarck, chancellor of the German Empire, played a large role in a critical deception prior to the war. In 1870, the Prussian army defeated France, prompted by well-timed suggestions and a fake telegram deceptively and intentionally crafted by Bismarck. The resulting alliances, created by Bismarck to protect his newly established German Empire, set the groundwork for World War I.

The hasty escalation of World War I was aided in part by some countries using treaties as a pretext to avenge losses from 19th-century skirmishes. Social distress brewed in the growing disconnect between the upper-class imperial mindset and middle- to lower-class socialist views. This tension also contributed to countries' desire to incite war. Some countries, including Germany and Britain, were hoping to unite restless populations behind a common, nationalistic goal, even if it had to be instigated indirectly. This deception involved the obstruction of motives, as countries tried to maintain an image that they were acting out of moral obligations to their allies, rather than to achieve their own ends.

## Propaganda

Propaganda was another key form of deception in World War I that was used to distribute information in support of a cause and manipulate public opinion. Leaders used it to evoke hatred against the enemy, enhance existing friendships with allies, create common ground with neutral countries, and demoralize the enemy. Used to mislead their own citizens as well as other countries, propaganda took on a variety of forms, from oral propaganda to newspapers and posters.

For example, while anti-German sentiment was on the rise in the United States at the outset of the war, public opinion was not unified. President Woodrow Wilson created the Committee on Public Information (CPI) in 1917 to promote the war

internally and make clear the United States' intentions abroad. Tapping into knowledge of psychology and advertising, the CPI launched what was then the largest modern propaganda campaign ever carried out. The CPI released guidelines for the media to report facts in a light that reflected positively on America's involvement. These guidelines were widely adopted by the media, largely because they wanted to stay in the information loop. The CPI monitored information dissemination and used various types of media, including photographs, leaflets, and films, to saturate information channels with propaganda.

One propaganda tactic was emotional appeal, which involved stirring up people's emotions and then manipulating those emotions into desired actions, such as donating to the war effort or enlisting in the military. Another propaganda method was demonization, which depicted the enemy as a ruthless aggressor. The goal of this technique in the United States was to fan the flame of anti-German sentiments. A common, and effective, execution of this type of propaganda was the use of atrocity stories, created by relying on the exaggeration of not necessarily substantiated material to arouse feelings of disgust and hatred. Another propaganda technique was the effort to appeal to niche intellectual groups, such as businessmen, teachers, and pacifists, with messages about the eventual benefit of the war. For instance, the War to End All Wars campaign came from this propaganda approach.

Typically, propaganda highlighted cultural differences. The scarcity of dual-language speakers was exploited because people could not readily access or understand propaganda from the opposition. Deceptive posters, articles, and photos left citizens with a false impression of their side's imminent success and the imperative role their actions would play in that success.

### Submarine Warfare and Deception

In Britain, World War I is considered the most popular war ever fought by that nation, and this opinion is attributed largely to effective propaganda. For example, the German decision to engage in unrestricted submarine warfare was used to develop propaganda. The Germans used submarines called U-boats, an abbreviation from the German *unterseeboot* meaning undersea boat,

to attack ships with the goal of cutting off Britain's communication and trade. Many British naval leaders likened this action to piracy, arguing that it was morally wrong to sink nonmilitary ships without warning, and this view was spread through the populace with various forms of propaganda.

The actual use of unrestricted submarine warfare was also a case of deception during the war. Civilian ships were led to believe they were safe because prior warfare conventions excluded civilian ships as possible targets and because there was no sure way of detecting or predicting an attack. The deception lay in the false sense of security created by traditional warfare that was undermined by surprise U-boat attacks. The nature of a surprise attack involves deception because the target is given no warning of the impending danger and the aggressor is intentionally focusing on nonmilitary ships. The use of unrestricted submarine warfare, employed both at the beginning and end of the war, with a brief respite in 1916 because of protests of its unjustifiable aggression, shattered wartime conventions of expected behavior between opponents and ultimately brought the United States into the war.

Both sides in the conflict engaged in deception regarding the RMS *Lusitania*. The *Lusitania*, a British ocean liner, set out from the United States to England on May 1, 1915. The fastest passenger liner at the time, travelers saw the *Lusitania* as the safest option for crossing the Atlantic. The Germans placed an advertisement in a newspaper the morning of the departure, warning passengers of the dangers of riding the boat: Germany suspected the *Lusitania* of transporting ammunition, making it a potential U-boat target. The captain of the *Lusitania*, William Turner, assured travelers that because it was a passenger ship, they would not be in danger. The *Lusitania* was sunk on May 7 by a German U-boat, resulting in the deaths of 1,195 people. The German suspicions of deception, however, were later confirmed: the *Lusitania* had in fact been carrying ammunition to the British. Turner's assurance that the ship was simply a passenger ship was false. Even so, the event ignited already growing anti-German sentiment in the United States and played a role in the eventual addition of America to the Allied forces.

### Zimmerman Telegram

New communication technologies also provided instances of deception. The Zimmerman Telegram (or Note) is one famous example and was another source of tension between the United States and Germany. President Wilson, in an effort to facilitate the peace process, granted Germany the use of a U.S. State Department cable between Berlin and the German embassy in Washington, with the stipulation that any cables sent over the cable must be related to the peace process. Choosing not to honor that condition, the German foreign minister, Arthur Zimmerman, used the cable to send a message to be passed onto the German minister in Mexico. The telegraph offered U.S. territory to Mexico in exchange for that nation's assistance in keeping the United States out of the war. Zimmerman requested that Mexico attack the United States from the southwest with the

goal of obtaining Texas, New Mexico, and Arizona. Zimmerman's hope was that the United States would be too occupied to join the war in Europe. Additionally, Zimmerman urged the Mexican minister to persuade Japan to join the German side. Germany not only ignored its agreement to use the cable peacefully but used it in an effort to incite action against the United States.

However, British cryptanalysts intercepted and decoded the telegram in January 1917. They did not wish to reveal the existence of their code-breaking room, so instead they relied on espionage to acquire the full text of the telegram in order to present it to the United States. A man who worked in the Mexico City telegraph office owed a favor to the British chargé d'affaires in Mexico and was happy to provide a copy of the telegram. The British revealed the telegram's contents to the United States on February 24, 1917. Deceiving through

*A drawing made for the New York Herald and the London Sphere, circa 1915, shows the R.M.S. Lusitania as a second torpedo hits behind a gaping hole in the hull on May 7, 1915. The sinking revealed a crucial, and tragic, deception that occurred during World War I. The British ocean liner set out from the United States to England on May 1 with assurances to the passengers that because it was a passenger ship, it was not an enemy target. In fact, the Lusitania had been carrying ammunition to the British as the Germans suspected, leading to its destruction by a German U-boat torpedo and the deaths of 1,195 people. The event further ignited anti-German sentiment.*

omission, the British withheld information from the United States for weeks after the telegram's discovery to allow American anti-German sentiment to continue to grow, particularly after the recent re-election of Wilson on the premise of neutrality. Wilson received the telegraph only a few weeks after he had cut off diplomatic relations between Germany and the United States in response to U-boat warfare. The Zimmerman Telegram was the final incident that drew the United States into the war alongside the Allies in 1917.

World War I began with an alliance network that had been slowly established over many years through smaller wars, nationalistic pride, and deception. Propaganda helped garner support for the war effort, employing deception to mold public opinion. The introduction of U-boats added a new form of deception and tactics to warfare, forcing countries to re-evaluate techniques, trust, and in the case of the United States, involvement in the war. Finally, the Zimmerman Telegram brought together the deceptive nature of the war with devious behavior by all parties. World War I was unlike any war that had been waged before, and deception was fully entrenched in the entire conflict.

## World War II

When it comes to studying deception as a tactic of war, World War II has proven to be the most useful case study in history. Both the Axis and the Allied forces routinely turned to lying and deceit to attempt to better position their sides for victory. World War II took place between 1939 and 1945 and involved a majority of the nations of the world—especially the major powers. A widespread war, nations placed their entire domestic capabilities into the effort, hoping to assure victory. Overall, between 50 and 70 million individuals perished during the six years of battles.

World War II was largely fought in two main theaters. In the Pacific Theater, Japan was working to gain complete control over East Asia, while the European Theater saw the rise of Nazi Germany and subsequent attacks against France and the United Kingdom. Later, Italy joined sides with the German forces. While the war formally began when Germany invaded Poland, the United States did not get officially involved until after the Pearl Harbor attacks in December 1941. The war in the European Theater came to a close when Polish and Soviet troops captured Berlin, forcing Germany into surrender. Japan later surrendered after two atom bombs were dropped by the United States, and the Soviet Union formally declared war.

### The Allies' Deceptive Tactics

During the war, both sides employed numerous operations and missions aimed at deceiving the enemy. Operation Bodyguard was an Allied plan launched during the buildup to the 1944 D-Day invasion of Normandy. The actual goal was to mislead the German command about the location and date of the invasion. Axis leaders—especially Adolf Hitler—were well aware that some form of invasion was likely to happen as a result of their actions in the region. As a result, coastal defenses were not particularly strong as Hitler aimed to defend every part of Europe from a possible attack. By convincing Hitler that Normandy was just a diversion, it would deflect crucial manpower from that area and make the invasion far easier on Allied soldiers. The Allied forces were successful in convincing Axis leaders that the invasion would come later and that it would be far more likely to occur through the

Pas-de-Calais, Balkans, or Norway. Once the invasion began in Normandy, Hitler still refused to move all troops from Pas-de-Calais, thinking that the Normandy landing was just a diversion. This was one of the most—if not the most—successful missions of World War II.

Operation Copperhead was run by British forces and inspired by the 1943 movie *Five Graves to Cairo*. Its mission was to contribute to the success of Operation Bodyguard by misleading German intelligence about the whereabouts of General Bernard Montgomery. Because Montgomery was a field marshal and one of the more well-known Allied leaders, German intelligence expected him to play a key role in any invasion. So British troops arranged a body double and had him make a series of high-profile appearances in Gibraltar and Algiers leading up to the invasion. The British hoped that if the Germans saw someone they thought was Montgomery in those locations, they would assume an invasion must not be imminent. While there is no clear proof that the operation had any great impact, it is one of the more creative efforts to deceive the enemy witnessed in World War II.

Operation Quicksilver was a major element of the Allied victory in World War II and focused on deceiving Axis forces in the European Theater (particularly Hitler). Quicksilver was a subplot attached to Operation Fortitude South, which was launched in 1944 to help detract German attention from the beaches of Normandy. Ultimately, the goal was to convince Axis leaders that any American invasion would occur at the Pas-de-Calais near the Strait of Dover. By creating such deception, Allied forces hoped to ensure a greater chance of victory by limiting the presence of Axis forces in the area of Normandy. The plan was thought up by Colonel David Strangeways, who was actually a specialist in military deception.

The primary tactic of Quicksilver was the creation of a fake element of the U.S. Army. German leaders—including Hitler himself—were, over time, convinced that there was an American army group preparing to land in the Pas-de-Calais for the major invasion that had long been expected. The group, fictitiously called the First U.S. Army Group, was allegedly training under General George Patton in the United Kingdom while finalizing details of the invasion. The key player in the

scheme was Joan Pujol Garcia. He was a double agent loyal to the Allies who supplied the Germans with all of the detailed information created by the Allied forces to help steer the Axis leaders away from their actual plans.

Operation Fortitude was another Allied deception that contributed to the success of Operation Bodyguard. Fortitude involved a North and South section aimed at misleading Axis leaders about the precise location of the forthcoming invasion. Rather than using radio communications to deceive, Fortitude created fake field armies to threaten Norway and Pas-de-Calais. This was perhaps the most important deception employed during World War II, as it diverted attention away from Normandy both before and immediately after the D-Day invasion.

Operation Accumulator was a naval operation organized by Allied forces in June 1944 intended to further support the initial invasion of France. The mission centered on two destroyers making false radio transmissions that they knew would be intercepted. The message transmitted was that there were engine problems that would lead to a delay in the invasion. German military forces, however, never responded to the transmissions, and even an Allied pilot seemed perplexed by the presence of the destroyers.

Operations Big Drum, Glimmer, and Taxable were all deception techniques carried out by Allied naval forces to support Operation Neptune (a plan to deceive the Germans about the invasion at Normandy in 1944). The operations involved small boats and aircraft running fake invasions, created through decoys, radar jamming, and wireless traffic, of Cap d'Antifer, Pas-de-Calais, and Normandy. The goal was to either convince the Germans that the invasion was about to happen somewhere beyond Normandy or that the invasion was not overly large. Ultimately, the success of these three operations cannot be authoritatively judged. While they unquestionably contributed to more confusion among the Axis powers, there was little immediate response from German forces. Operation Titanic was another element of D-Day, orchestrated by Allied air forces to drop dummy parachutists into drop zones far away from the actual drop zones. The hope was that the Germans would think the invasion force was significantly larger than it actually was.

Operation Hardboiled was a 1942 deception plan created by the London Controlling Section aimed at tricking the Germans into thinking there was a strong invasion threat in Norway. It was one of the least useful deception plans undertaken by Allied forces, because of a lack of enthusiasm among leadership and troops alike. Because of the number of double agent threats, it had to be planned and prepared for as a real mission that would actually never come to be. Despite invasion never actually taking place, Hitler did opt to reinforce the Scandinavian region in the immediate aftermath of learning of Operation Hardboiled.

Operation Bertram was carried out by Allied forces in the Middle East in 1942. The goal—like many other World War II deception plans—was to confuse German military commander Erwin Rommel about the timing and location for an upcoming Allied attack. To do so, Allied troops created the appearance of army units in areas where there were none and also concealed armor and artillery in other areas. By selectively moving vehicles forward and disguising them, Rommel was led to believe that an attack was ready to be launched, causing him to be unprepared to defend. When the attack began, it was too late.

Operation Cascade occurred in 1942 while British forces in the Middle East were at their weakest point in the war. Given the limited strength of operations at the time, deception was used to convince Axis leaders to not attack. By using false troop formations, radio traffic, and a series of double agents, the British were able to confuse Axis leaders about how many troops they actually had, making an attack unlikely.

Operation Barclay worked to help the Allied invasion of Sicily in 1943. The goal was to deceive German and Italian powers about where the invasion would come from. The Allies used fake troop movements, radio communications, and interpreter recruitment to point toward a Balkan invasion. Most important, the Allied forces created a fake army with 12 divisions. Hitler fell for the deception and increased Axis presence in the eastern Mediterranean, which made the invasion of Sicily a definite surprise for the nonexpecting enemy.

Operation Mincemeat was a British disinformation campaign carried on during the war in conjunction with Operation Barclay. With the

Allied forces planning to invade Sicily in 1943, Operation Mincemeat aimed to convince German commanders that the actual targets were Greece and Sardinia. In order to successfully do so, Allied leaders allowed the Germans to think they had found secret Allied documents that discussed details of war plans and tactics. In order to do so, the British pinned the documents to a corpse and had it wash ashore where Germans would be sure to find it. The hope was that such a tactic would come across as less likely to be undertaken by the enemy.

Operation Cockade involved a series of deceptions by the Allied forces to remove German pressures on Allied and Soviet troops. Strategically, this operation aimed to use fake attacks in western Europe to cause Axis leaders to move troops and supplies. The main objective, however, was to force the Luftwaffe into a large-scale air campaign against the British and American air forces that would lead to Allied air superiority over all of Europe.

Operation Scherhorn was a deception plan utilized against Nazi leaders between 1944 and 1945. It had originally been created by Josef Stalin. The objective was to give the illusion of a large German group plotting behind the front line in Russian territory. When Nazi intelligence resources came out to help the troops, Russians would capture them and in the process limit intelligence resources.

### **The Axis Powers' Use of Deception**

It was not just Allied forces that utilized deception as part of their war strategy; Axis forces used this tactic as well. For example, the Gleiwitz incident occurred on the evening before Germany's invasion of Poland in 1939. A series of Nazi soldiers posed as Polish citizens and staged an attack against a German radio station. The hope was to create the appearance of aggression being shown against Germany by Poland in the immediate time frame before Germany invaded. Nazi leadership pushed for numerous propaganda events, such as the one at Gleiwitz, to win the battle over public opinion.

Operation Harpune was a major German plan in 1941. At the time, Germany was putting all of its internal efforts into Operation Barbarossa (which was the invasion of the Soviet Union) and

needed a distractor so as to not give its strategy away. Operation Harpune was a propaganda push aimed at convincing Allied leaders that Operation Seelowe (the invasion of Great Britain by ground troops) was inevitable. The original intent was to run the fake invasion on multiple days (turning about each time) to cause great confusion among the British. Likewise, a German cruiser would use diversionary tactics near Iceland to add to the confusion, and another German cruiser would raid merchant shipping in the Atlantic. If the Germans had had the necessary manpower and air dominance needed for Operation Seelowe to work, Operation Harpune might have been a key ingredient for a potential German occupation of Great Britain.

Operation Kremlin was another successful German deception operation conducted in 1942 against Soviet forces. At the time of the operation, German forces were planning to begin staging a series of attacks to eliminate Soviet forces in the southern sector of the Eastern Front. But they knew focusing all of their energies on this tactic would tip off the Soviets to their plans. As a distraction, German leaders ordered troops at the earliest time possible to restart a series of large-scale attacks on Moscow. Despite there being no actual intention to move the focus toward Moscow, Soviet leaders were very concerned about the news. It aligned with what they thought Germany would do, and it also matched with previous German behavior. To really sell the threat as legitimate, Germany ordered the Luftwaffe to practice more reconnaissance flights, and Soviet prisoners-of-war were asked numerous questions about the possible defense of Moscow before being released. While the actual success of Operation Kremlin when considering the overall war can be questioned, it undoubtedly registered with Soviet leadership and caused them to alter their strategic plans.

Funkspiel was a counterespionage operation carried out by Nazi forces during the war. Operationally, Funkspiel involved capturing radio operators in France and forcing them to send false messages to Allied leaders. Further, the operators allowed Nazi troops to intercept valid Allied information. The plan was successful until May

1944, when the British discovered the plan and started feeding back incorrect information to confuse Axis leaders.

Operation Blumenpflucken was a major Axis deceit scheme carried out in late 1944 in Norway. Planned by Ernst Weiner, the aim was to break down the Norwegian resistance to Axis occupation. The goal was to capture and kill random Norwegians instead of attacking actual resistance leaders. By doing so, the Axis powers intended to place the blame on resistance leaders for the killings, causing a domestic backlash against them. Ultimately 11 Norwegians were killed, and many across the globe continued to incorrectly blame the resistance movement well into the 1990s.

What emerges from this brief overview is a clear picture of how widespread deception was a military tactic during World War II. With nearly equal bases of power and supplies, the outcome ultimately became a matter of psychological operations that pitted the Axis and Allied powers in a strategic battle unlike anything ever witnessed in the history of the world.

# Glossary

---

**Absence of information:** A flaw in human reasoning in which people asked to make judgments based on specified information seldom think about the fact that other, important information might not be supplied to them.

***Ad hominen* attack:** A logical fallacy in which a person makes a personal attack on his or her opponent rather than addressing their argument.

**Advance fee scheme:** A type of fraud in which a person is induced to pay for access to an opportunity that is promised to provide even greater rewards, for example, paying for information to set up a work-from-home business, only to find that the real probability of earning money in the proposed manner is nonexistent or minimal.

**Affinity group fraud:** Fraud that targets members of a group that share characteristics with the person perpetrating the fraud, such as ethnicity or religion, with the implication that the perpetrator was a particularly trusted member of the group. Bernard Madoff's Ponzi scheme is often cited as an example of affinity fraud because he is Jewish, as are most of his victims.

**Anchoring:** A cognitive strategy that can lead to incorrect judgments by making estimates beginning with some starting point, then adjusting

that estimate upward or downward. The original starting point may exert a strong influence on the final estimate or judgment because the person is reluctant to abandon it, even if evidence suggests that they should.

**Argument from ignorance:** A logical fallacy in which something is asserted to be true because it has not been proven false.

***Art of War, The:*** A Chinese treatise, probably written between 500 and 300 B.C.E., attributed to the military official Sun Tzu; the treatise also includes commentary by 11 other writers, added over a period of centuries after the original writing. It includes one section on deception in military operations, which Sun Tzu says is a requirement of military strategy, and also discusses the usefulness of military deception in many other sections.

**Automatic writing:** A purported psychic phenomenon in which an individual touches a sheet of paper with a writing implement and the implement is said to write out messages of its own accord.

**Availability rule:** A type of bias in estimating the probability of some event, in which people judge as more common the events they can easily imagine or

for which they already have numerous memories. For instance, someone whose mother died of lung cancer is likely to judge the risk of smoking as higher than someone who does not know anyone with lung cancer, although the personal knowledge has no bearing on the actual risk.

**Base rate fallacy:** A fallacy in which a person ignores information about the base rate, or prior probability, of an event in making a judgment about a single event.

**Begging the question:** A type of fallacy in which the premise assumes the conclusion rather than proving it.

**Bias for causality:** The tendency of people to create causal explanations for random situations as a way of making sense out of their lives, a fact that makes it difficult to discard beliefs that are incorporated into such explanations, even if those beliefs are based on evidence that has been discredited.

**Big Lie:** A propaganda technique used in Germany in the Nazi era, traced back to 1925 when Adolf Hitler described a form of this technique in *Mein Kampf*. The concept of the Big Lie was popularized by Joseph Goebbels, the Nazi minister of propaganda, who said that it was possible to convince people of a lie if it was big enough and repeated often enough.

**Bilocation:** The ability of a person or object to be in two places at once, a power claimed by various magicians and religious figures.

**Boy-who-cried-wolf syndrome:** The tendency for someone who is known to lie or exaggerate to not be believed when he or she is telling the truth. The reference is to one of Aesop's fables, in which the people of a village ignore a shepherd boy's cries for help because in the past he repeatedly made false claims that his flock was being attacked by a wolf.

**Cambridge investigation:** An 1857 event in which several well-known mediums attempted to claim a \$500 prize offered by a newspaper, the *Boston Courier*, if they could produce evidence

of spiritualistic phenomena to the satisfaction of three Harvard professors: Louis S. Agassiz, E. N. Horsford, and Benjamin Pierce. No satisfactory evidence was produced, and the prize remained unclaimed. The event is named after the location of Harvard University, which is in Cambridge, Massachusetts.

**Cardiff giant:** A stone sculpture created by George Hull and buried in the ground near Cardiff, New York, in 1869. The "giant" was discovered by workmen and became a popular attraction, believed by some to be the petrified remains of a human giant. Upon closer examination, it was declared a fake, but the public continued to pay to see it.

**Chain referral scheme:** *See* pyramid scheme.

**Circular reasoning:** A type of logical fallacy in which the evidence for the validity of an assertion assumes that validity; in effect, it assumes what it claims to prove.

**Cognitive dissonance:** A psychological concept explaining the discomfort that a person experiences when one of their beliefs is contradicted by their experiences or other evidence. In order to reduce this discomfort, the person may change their beliefs to reflect reality, or may reject the evidence of reality in order to hold on to their beliefs.

**Concealed information test:** A method of questioning introduced in the 1950s to determine the truthfulness of someone's claim that they were involved in a crime; the test determined whether the person who was questioned had information that only someone involved with the crime would have.

**Cottingley fairies:** A famous hoax that fooled, among others, Sir Arthur Conan Doyle, who wrote an article about them in 1920. The basis of the hoax was a series of photographs of fairies, which were later shown to be paper cutouts from a children's book.

**Cramming:** A type of fraud in which small charges are added to a legitimate bill, such as for phone service, usually by a third party.

**Crop circles:** Geometric patterns created in grain fields that began appearing in the United Kingdom in 1979 and have appeared in many other countries since. Initially claimed by some as evidence of visitors from outer space, they were later revealed to be the work of two Englishmen and other people who imitated them.

**CSI-COP:** The Committee for Scientific Investigation of Claims of the Paranormal, an organization founded in Buffalo, New York, in 1976.

**Eyewitness:** Someone who has direct knowledge of an event, such as by hearing or seeing it. In the law, eyewitness testimony has traditionally been considered strong evidence, although psychological experiments have demonstrated that eyewitnesses are far from infallible and the memory of events can be manipulated by questioning or by the later introduction of other information about the events.

**Fakelore:** Manufactured folklore presented as if it were traditional. The term was coined by Richard M. Dorson to describe American legends such as Pecos Bill and Paul Bunyan, which were known to have been created by particular writers rather than being characters in authentic traditional tales.

**False memory syndrome:** A condition in which a person strongly believes in memories that are in fact untrue; the term was popularized in the 1990s by Pamela and Peter Freyd, who were accused by an adult daughter of childhood sexual abuse. The Freyds' contention, shared by many psychologists, is that false memories can be created during the course of memory therapy, and the patient has no way to distinguish between false and true memories.

**Federal Trade Commission:** A U.S. regulatory agency established in 1914 by the Federal Trade Commission Act and charged with protecting consumers from deceptive advertising and ensuring fair and ethical competition among businesses.

**Flashbulb memory:** A detailed, vivid, and accurate memory of a moment in a person's life,

analogous to that which would be captured by a photograph, were a photograph able to prioritize certain details over others. Despite many claims of flashbulb memories, generally in connection with some major, emotionally arousing event (e.g., receiving news of the assassination of President John F. Kennedy), not all psychologists believe that they are different from other memories, or that they are particularly accurate or stable.

**FOAF:** An acronym for "friend of a friend," a source often cited in urban legends. The point of FOAF stories is that their veracity is automatically suspect, although possibly believed by the teller because the source of information is so distant from the teller—it didn't happen to them or to someone they knew, but rather to someone two connections removed from them.

**Forced feedback:** A technique to plant false memories in a person's mind by presenting the person with a fictional summary of an event that actually occurred. Psychologist Elizabeth Loftus developed this technique to demonstrate how false memories could be planted in individuals; often, her subjects accepted her false version of events as true and part of their actual experience, and some would make the false version of events more vivid in recalling them than they were as originally presented to them.

**419 fraud:** Also known as the Nigerian fraud, a scam operated by mail or e-mail in which an individual receives a message purportedly from a government official, asking them to send money or reveal confidential information (e.g., bank account number) in order to receive a percentage of a sum the author is trying to transfer out of their country. The name refers to section 419 of the Nigerian criminal code, which is violated by this type of fraud.

**Gambler's fallacy:** A mistaken belief that the laws of probability will hold true in the short run as well as the long run and/or the related belief that independent events are affected by previous events. For instance, if a fair coin is flipped five times and heads result each time, one may believe that the next flip is more likely to be tails, when in fact heads and tails are equally likely on each flip.

**Hindsight biases:** Biases that frequently emerge when evaluating intelligence reports, including overestimation of the accuracy of past judgments, underestimation of how much has been learned from intelligence reports, and the tendency to believe that events were more foreseeable than they really were.

**Identity theft:** A criminal act in which a thief obtains information (e.g., social security numbers or credit card numbers) that allows them to assume another person's identity; the information is then used for other criminal activities, such as stealing from the individual's bank account.

**Ignoranti elenchi:** A logical fallacy in which an argument is not relevant to the issue under discussion; the argument itself may or may not be valid.

**Illusory correlation:** Assigning causal explanations to observed covariation that may in fact be due to chance or other factors not considered.

**Lake Wobegon effect:** The result found in many standardized testing situations in schools, in which most or all the children are found to be performing above average. Since in the long run about half should be above average and about half below, if most or all are found to be above average, this suggests that the results are invalid due to teaching to the test, score inflation, teacher cheating, etc. The name refers to the fictional Lake Wobegon featured on Garrison Keillor's radio program *A Prairie Home Companion*, where "all the children are above average."

**Law of small numbers:** A humorous label applied to the common tendency to overvalue information gained from small samples of data without taking into account the high degree of variability in data points. The name reverses the law of large numbers, a true principle in statistics that a sufficiently large sample can provide a good estimate of the characteristics of a population.

**Letter of credit fraud:** A type of fraud in which an individual is offered the opportunity to invest in a letter of credit and is promised large investment

returns. However, it is impossible to invest in a letter of credit because it is simply a guarantee issued by a bank in connection with goods shipped internationally.

**Liar paradox:** A sentence of this type: "This sentence is a lie." This paradox has been discussed by philosophers since ancient times because it is at once true and false.

**Malingering:** Fabricating information for personal gain by drawing attention to oneself or by harming someone else.

**"Man-who" syndrome:** An example of the tendency for information with a personal connection to be overvalued in comparison with abstract information. For instance, statistical evidence of the dangers of tobacco consumption may be ignored because a person knows a man who smoked for years and never got sick.

**Medicare fraud:** Fraud that makes improper claims to be paid by the Medicare system, the U.S. system of health insurance for people over age 65 or those with disabilities. Examples include billing for medical equipment that is not needed, billing for unneeded tests, or billing for services never performed.

**Misinformation effect:** A concept developed by Elizabeth Loftus in 1978 and later, in which recall of an event may be adversely affected by other information presented between the time an event is encoded in memory and the time it is recalled. Hence, eyewitness recall of an event may be affected by irrelevant or false information received by the witness after the fact, such as hearing descriptions of the event by others.

**Nigerian fraud:** *See* 419 fraud.

**On the Witness Stand:** A book published in 1908 by the German American psychologist Hugo Münsterberg, detailing the results of psychological studies suggesting that eyewitness testimony was not as infallible as commonly believed.

**Online auction scam:** A financial fraud committed over the Internet, in which someone runs an

auction on a Web site, such as eBay, and accepts payment but never delivers the advertised goods or delivers goods less valuable than those that were advertised.

**Operation Dirty Play:** An investigation carried out in 2011 and 2012 by the Broward County, Florida, Sheriff's Department into betting on youth football games. The operation ended with the arrest of nine men and the allegation that young players had been bribed to affect the outcomes of games.

**Othello error:** Falsely accusing a truthful person of lying, based on a predetermined view that the person is lying and by discounting other explanations (e.g., stress) for their apparently suspicious behavior. The reference is to Shakespeare's play, *Othello*, in which the title character misjudges his wife's reaction to the death of another character and believes her to be unfaithful to him.

**Overestimation of predictability:** A cognitive bias in which people are likely to believe that the actions of other people or groups are intentional and result from centralized planning, failing to realize that chance and coincidence often play a large role in the outcome of real-life events.

**Persistence of discredited evidence:** The principle that impressions based on experiences or other evidence are difficult to discard, even if the evidence has been discredited. This is true even in experimental situations in which a test subject is informed that they took part in a manipulated situation, and it is even more persistent in the real world, in which truth and falsehood may be much more ambiguous.

**Phishing:** A type of fraud committed over the Internet, in which an e-mail appears to come from a legitimate company or financial institution and tells the recipient that he or she needs to supply confidential information in order to straighten out a problem with their bank account, credit card account, or other financial institution.

**Polygraph:** A machine that is used to detect whether a person is telling the truth or lying,

hence the popular name "lie detector." Attached to the person answering the questions, the device detects physiological changes such as pulse and blood pressure, which are believed to be beyond conscious control; however, scientific research does not support the accuracy of polygraph testing.

**Ponzi scheme:** A type of fraud in which high financial returns are promised for investment in a business, whereas in fact the only income is provided by new investors. A Ponzi scheme can work for some time, but generally falls apart when it runs out of new investors or the amount of money owed to investors becomes too great. One of the most famous Ponzi schemes of the 20th century was perpetrated by Bernard Madoff, a New York investment advisor who was convicted and sentenced to 150 years in prison in 2009.

**The Prince:** A 1532 treatise written by Italian political theorist Niccolò Machiavelli that discusses how to achieve and maintain authority. Rather than endorsing an absolute set of ethical principles, Machiavelli advises that leaders suit their actions to the situation, giving rise to the term *Machiavellian* to describe ruthless, deceptive behavior.

**Psychic surgery:** A fraudulent practice in which a performer claims to perform surgery on a patient with her or her bare hands and without breaking the patient's skin, while in fact doing sleight-of-hand tricks and presenting blood or tissue from an animal. One well-known practitioner was Tony Agpaoa, who began his practice in the Philippines, and was arrested in 1968 in the United States on charges of medical fraud.

**Pump and dump:** A type of financial fraud in which the price of a security is artificially inflated (the "pump") through increased trading volume (often by inducing investors who are not a part of the scheme to buy the security), then sold before the price falls (the "dump").

**Pyramid scheme:** Also known as chain referral schemes, a type of fraud in which a person pays to distribute or franchise a product, but the only real money comes from the sale of the franchises or distributorships.

**Radiocarbon dating:** A method used to establish the approximate age of objects, often used when investigating suspected art or antiquities fraud. The technique is based on the fact that organic materials contain carbon-14, which decays at a steady rate; the amount of carbon-14 remaining in an object can therefore give an approximation of how old it is.

**Realism:** A philosophical point of view that states that the world exists independently of human descriptions of or thoughts about it and that people's thoughts refer to this actual world, so that they may be objectively judged true or false.

**Recovered memory therapy:** A type of psychotherapy aimed at helping a patient recover memories of abuse that were not previously accessible to their conscious mind. Recovered memory therapy is based in part on the finding that about 10 percent of abuse victims forget the abuse, but it is controversial because scientific studies have shown that it is possible to "plant" false memories that an individual cannot distinguish from memories of their actual experiences.

**Red herring:** A device used in speech and writing to distract people from the true subject of an argument.

**Scudder's American Museum:** An entertainment hall opened in 1842 in New York City by P. T. Barnum. The museum included a variety of exhibits, from live animals to freak shows; among the more famous attractions were the Fiji Mermaid and the Siamese Twins Cheng and Eng.

**Shattered Glass:** A 2003 film written and directed by Billy Ray, based on an *Atlantic Magazine* article by Buzz Bissinger, chronicling the career of *New Republic* journalist Stephen Glass, who was found to have fabricated many of the stories that he wrote while working for the magazine. The film details the lengths to which Glass—who had formerly worked as a fact checker—went to create a false trail of evidence that would make his stories appear genuine and the personal dynamics within the newsroom that facilitated his deceptions.

**Shifters:** A short-lived Ponzi scheme seen in the United States in 1922, in which college students became members of an organization called the Shifters, paid an initiation fee, and then sought other people to become members in order to make their money back. Various merchandise, such as pins and hats, was also marketed to members.

**Snopes.com:** A Web site run by Barbara and David Mikkelsen that collects urban legends and rates them as true, false, or undetermined, supplied with available evidence in support of their decision.

**Spectrographic analysis:** A method used to investigate suspected cases of art fraud. The technique involves removing a tiny sample of paint, burning it in a flame, and analyzing the resulting spectrum to determine if the paint includes materials not available at the time that the painting was claimed to be created or materials not known to be used by the supposed painter of the work.

**Strawman fraud:** A type of fraud based on the incorrect belief that the U.S. Treasury Department has bank accounts in the name of every U.S. citizen that can be accessed through a procedure known to the person perpetrating the scam. One feature of such scams is that the victim is told to specify their name in all capital letters.

**Telemarketing fraud:** A type of fraud in which someone is contacted by telephone and induced to send money or release confidential information, such as their bank account or credit card number, in order to collect a "free prize" or some other inducement.

**Thermoluminescence:** A method of dating pottery, often used to examine suspected forgeries. The technique is based on the principle that pottery loses its radioactivity when fired but gradually reabsorbs radioactivity from its surroundings. When heated to over 640 degrees Fahrenheit, pottery emits a glow that is brighter in older samples; hence, the glow emitted by a suspected fraud can be compared with that from another of known age.

***To Tell the Truth:*** An American television program aired from 1956 to 1968 on CBS and revived in 1991 by NBC. The concept of the show is that a celebrity panel tries to determine which of three contestants is telling the truth about their identity by asking them questions. The true contestant must give true answers, whereas the other two are allowed to lie to try to convince the panel of their identity.

**United Nations Convention against Corruption:** An international legal instrument adopted by the United Nations General Assembly in 2003 and entered into force on December 14, 2005. Among other things, the convention requires countries to make corrupt acts illegal and to cooperate with other countries in the prevention, investigation, and prosecution of corruption.

**Urban legend:** A type of modern folklore common in industrialized societies in which stories are passed from person to person (often through e-mail). The original source may or may not be known, and the sender may or may not believe the story to be true. The term was popularized by Jan Harold Brunvand in a series of books, beginning with *The Vanishing Hitchhiker: American Urban Legends and Their Meanings*, in 1981.

**Vividness criterion:** A bias in the evaluation of evidence, in which human thinking and memory is more affected by information that is

vivid, concrete, and directly perceived, than by abstract information experienced secondhand (e.g., by reading about it) that may actually have more value and hence should be given greater consideration.

***War of the Worlds:*** A radio drama written by Orson Welles, adapted from H. G. Wells's novel of the same name and aired on CBS radio in 1938. The radio show, which tells of a Martian invasion, imitates a series of news bulletins. Many listeners did not realize that they were listening to a fictional program and panicked, believing the invasion to be real.

***When Prophecy Fails:*** A book published in 1956 by American psychologists Leon Festinger, Henry W. Riecken, and Stanley Schachter, demonstrating cases of cognitive dissonance in members of a cult who believed that the world was about to end. When the world did not end on schedule, rather than discard their beliefs, the cult members were reinforced in them.

**White lie:** A lie that is unimportant and told with good intentions, for instance to spare someone's feelings or for the sake of politeness, rather than to maliciously deceive a person.

## The Prevalence of Lying in America: Three Studies of Self-Reported Lies

Kim B. Serota, Timothy R. Levine, & Franklin J. Boster

Department of Communication, Michigan State University, East Lansing, MI 48823, USA

*This study addresses the frequency and the distribution of reported lying in the adult population. A national survey asked 1,000 U.S. adults to report the number of lies told in a 24-hour period. Sixty percent of subjects report telling no lies at all, and almost half of all lies are told by only 5% of subjects; thus, prevalence varies widely and most reported lies are told by a few prolific liars. The pattern is replicated in a reanalysis of previously published research and with a student sample. Substantial individual differences in lying behavior have implications for the generality of truth–lie base rates in deception detection experiments. Explanations concerning the nature of lying and methods for detecting lies need to account for this variation.*

doi:10.1111/j.1468-2958.2009.01366.x

Humans are ambivalent about deception. On one hand, virtually all human cultures have some prohibition against lying. On the other hand, the ability to deceive well may be essential for polite interaction and, at times, self-preservation. Considerable research exists on the topic of deception, yet surprisingly little is known about the base prevalence of deception. Instead, much of this research has relied on untested assumptions and anecdotal evidence or on a few studies with small and nonrepresentative samples.

The dearth of deception prevalence research is a symptom of a broader systemic concern regarding research in the social sciences. Asch (1952, reprinted 1987) observed that “before we inquire into origins and functional relations, it is necessary to know the thing we are trying to explain.” Influenced by Asch, Rozin (2001) argued that social scientific research often emphasizes experimental studies and formal hypothesis testing to the exclusion of more basic descriptive work. In line with Rozin’s critique, more than 30 years of experimental detection research has proceeded without much attention to the basic nature of the phenomena itself. We believe that inquiry into deception and related behaviors associated with deception detection requires basic descriptive research examining the extent and distribution of deceptive communication in the population. In the extensive literature on deception,

the question of prevalence remains without a clear, well-documented answer. Thus, our research investigates reports of how often people lie.

In order to study the prevalence of lying, it is necessary to consider what constitutes a lie. Simply and broadly put, lying occurs when a communicator seeks knowingly and intentionally to mislead others. Ford, King, and Hollender (1988) suggest the “consciousness of falsity” to distinguish “normal” lies from pathological ones. Thus, it is not sufficient that something is false for it to be a lie; it is the intent that distinguishes the lie. As Bok (1999) observes: “The moral question of whether you are lying or not is not *settled* by establishing the truth or falsity of what you say. In order to settle this question, we must know whether you *intend your statement to mislead*” (p. 6).

Bok (1999) argues for the principle of veracity that involves a moral asymmetry between honesty and lies. Lying requires justification, whereas truth telling does not. Given prohibitions against deceit, people may try to avoid situations in which there is pressure to lie. Research finds that this principle of veracity guides everyday communication and people consider using deception only when the truth is problematic (Levine, Kim, & Hamel, 2009). But this tells us about the situations in which people lie and not how often people lie.

Despite this moral asymmetry, most deception research has presumed the ubiquity of lying and moved past the question of frequency to focus on the behavioral correlates of lying or lie detection. The frequency question remains mostly unanswered. A notable exception, and the best and most cited prevalence research, however, is the 1996 diary study of lying in everyday life by DePaulo, Kashy, Kirkendol, Wyer, and Epstein (1996). Using two small samples, students and recruited members of the local community, DePaulo et al. reported the mean number of lies per day as 1.96 ( $SD = 1.63$ ,  $N = 77$ ) for the students and 0.97 ( $SD = 0.98$ ,  $N = 70$ ) for the subsequent nonstudent sample. Importantly, the aim of the second sample was to replicate findings regarding the nature and reasons for lying with a different but not necessarily representative sample of the population. Nonetheless, a brief synopsis of this study in *Psychology Today* (“The Real Truth About Lying,” 1996) reported that DePaulo conducted research to answer the question “how often do people lie . . . ?” and in many subsequent research reports the finding *that people tell one to two lies per day* has been reified.

More recently, two smaller and lesser-known studies have sought to replicate and extend elements of the DePaulo et al. (1996) diary study. Hancock, Thom-Santelli, and Ritchie (2004) examined differences between reports of face-to-face lies and reports of lying through computer-mediated communication. Results from a student sample yielded an average of 1.58 lies per day ( $SD = 1.02$ ,  $N = 28$ ) and a significant difference for the rates of lying (lies as a proportion of interactions) between face-to-face, telephone, instant message, and e-mail interactions; the highest rates occurred during phone conversations and the lowest rates with e-mail. George and Robb (2008) replaced the pencil-and-paper diary with a personal digital assistant (PDA). They report fewer lies per day;  $M = 0.59$  ( $SD = 0.37$ ,  $N = 25$ ) with the 10-minute

definition of interaction used by DePaulo et al. and  $M = 0.90$  ( $SD = 0.54$ ,  $N = 25$ ) in a second study shortening the interaction definition to 5 minutes (increasing the number of reporting opportunities). Thus, the current literature provides estimates ranging from 0.59 to 1.96 lies per day. Variation in estimates from study to study is expected due to small sample sizes and large standard deviations.

Other broad estimates of prevarication cited by deception researchers have come from nonacademic sources. In a poll conducted for the book *The Day America Told the Truth* (Patterson & Kim, 1991), 90% of the subjects admitted being deceitful about a list of subjects, the most common being true feelings, income, accomplishments, sex life, and age. In a *Reader's Digest* poll (Kalish, 2004) of 2,861 of the magazine's readers, 93% reported one or more kinds of dishonesty at work or school, 93% reported one or more dishonest acts in the market place, and 96% reported lying to or committing other dishonest acts toward family and friends.

Some studies report on various facets of prevalence but provide limited insight into the overall extent of lying because they deal with specific situations such as lying by job applicants, students lying to parents, or lying about spousal infidelity. Levashina and Campion (2007) found that 90% of undergraduate job candidates used some form of deception during job interviews; however, the distinction between impression management and outright lies is often blurred and their report notes that behaviors that are semantically close to lies are difficult to confirm. They estimate actual lies occur in the wide range of 28–75% of job interviews. Jensen, Arnett, Feldman, and Cauffman (2004) examined lying to parents by adolescents and young adults, and quantified the extent of lying by topic over the course of a year. This study found that 82% of all students reported lying to their parents on at least one of six topical issues (money, alcohol/drugs, friends, dating, parties, and sex) with the mean incidence of lying ranging from 0.6 to 2.4 lies depending on the issue. Much of the research that seeks to quantify lying behavior is concentrated in the area of relational communication. Cochran and Mays (1990) studied dating dishonesty among college students and found that 60% of women claimed to have been lied to in order to obtain sex, whereas 34% of the men in the study admitted lying to obtain sex. Knox, Schacht, Holt, and Turner (1993) found that 92% of students (when given the opportunity to report anonymously) admitted to lying to a current or potential sexual partner.

It is not difficult to understand why many scholars believe lying is a frequent event. Life experiences and anecdotal evidence encourage acceptance of the proposition. A typical research report discussion statement illustrates this view: "Lying is ubiquitous and comes in many forms, from cherished beliefs about Santa Claus to the self-deception commonly encountered in the treatment situation" (Tosone, 2006).

General acceptance of the ubiquity assumption has implications for studies on lying and deception detection. If everyone lies and lying is an everyday occurrence for most people, this would suggest that individual differences should not have much influence on the identification of lying behaviors. If this is the case, it should be possible to understand the nature of lying and deceptive behavior and find ways to

detect it by studying anyone telling lies. For example, this presumption is recurrent in studies that look for regularities in nonverbal cues, microexpressions, and the leakage of emotions. Individual differences are typically considered of less relevance than situational considerations such as whether the lie is a minor everyday lie or if the lie is a consequential, high-stakes lie. If, on the other hand, base rates for lying (the frequency with which one lies or the ratio of truths to lies) vary across groups of individuals or if the ubiquitous average masks variation that is not normally distributed in the population, researchers looking into the nature of the phenomenon need to take into account this variation. Research designs and sample selection procedures ought to control for this variation, or they should examine the nature of the variation itself. Consistent with this second possibility, recent meta-analysis suggests substantial individual differences in people's ability to lie convincingly (Bond & DePaulo, 2008).

### Study 1

Examination of the literature reveals few attempts to document the extent to which everyday lies occur. The few studies that offer behavioral rates have performed so as an adjunct to the main objectives of the research and the rates obtained are restricted to the specific conditions of the studies. This situation is exemplified by the DePaulo et al. (1996) studies. Although lie frequency is among the interests that prompted their research, most of the design and analysis is devoted to the topics of what people lie about, to whom they lie, and what motivates them to lie. DePaulo et al. noted that their observations of lying frequency are based on students and an adult sample that was chosen not for representativeness but, instead, to provide a dissimilar sample in order to determine whether or not the results from the student sample could be replicated. Still, DePaulo et al. reported: "Participants in the community study, on the average, told a lie everyday; participants in the college student study told two." So despite being based on data that were (correctly) noted by its authors as lacking generalizability, this research report has become the standard reference for the prevalence of everyday lies in the deception literature. The goal of Study 1 is to test this claim by obtaining data from a large cross-section of the adult population.

### Method

#### *Participants and design*

In order to examine the proposition that most people tell one to two lies per day with projectable data, an Internet survey of 1,000 American adults (18 years of age or older) was conducted using the Synovate *eNation* omnibus panel.<sup>1</sup> The omnibus panel is a commercial survey research tool used for daily, multiclient studies and approximates a nationally representative sample with some limitations. Panelists are recruited into a pool of more than 1 million subject households using banner advertisements, mailing lists, and related procedures to promote participation; subjects must formally opt-in to confirm awareness that they are participating in research and consent to participation. Each survey day, a new sample ( $N = 5,500$ ) is drawn from the pool.

Subjects are randomly selected within strata defined by population characteristics. The response rate is typically 19–20%, accounting for both nonresponse and incomplete surveys. Responses exceeding the 1,000 daily quota are deleted using systematic (random start,  $n$ th selection) sampling. The panel is matched on age, gender, income, and region to the U.S. Census Bureau's monthly *Current Population Survey* (CPS; U.S. Census Bureau, 2008). Results are poststratification weighted (Kish, 1965) to these CPS criteria. In addition, Synovate uses weighting in order to adjust partially for underrepresentation of Hispanics and ethnic minorities in the sample. Subjects were included in a prize drawing as the incentive to participate. Table 1 provides the unweighted and weighted sample demographics and compares them to recent U.S. Census data and to *eNation* weighting targets, which are based on U.S. Census data.

This study used a nonexperimental survey design in order to obtain descriptive measures for the incidence of lying in the population. Results from this survey are compared with the popular standard established by the DePaulo et al. (1996) studies.

#### *Procedure and measures*

Subjects received an invitation e-mail asking them to participate in an omnibus survey on the date of the study. The invitation was directed to a specific member of the household identified by age and gender. The invitation instructed that individual to click on a link to the survey website. When subjects accessed the site, they were provided with instructions, asked questions confirming participant identification, asked the omnibus survey questions for several unrelated topics, and asked a series of demographic questions. On the day of the lying study, subjects were asked about four topics (in order of presentation): packaged meals, cat litter products, lying behavior, and water softeners.

The DePaulo et al. (1996) diary study (and subsequent diary studies) used subject training to make the topic less sensitive and provide the subjects with a common definition of lying. Training of survey respondents was not possible, so to encourage accurate reporting, the self-report lying question was preceded by a definition of lying that incorporated the elements of foreknowledge and intent described at the beginning of this article. A brief description of types of lies was also included. Both were presented in a nonpejorative manner:

We are interested in truth and lies in people's everyday communication. Most people think a lie occurs any time you intentionally try to mislead someone. Some lies are big while others are small; some are completely false statements and others are truths with a few essential details made up or left out. Some lies are obvious, and some are very subtle. Some lies are told for a good reason. Some lies are selfish; other lies protect others. We are interested in all these different types of lies. To help us understand lying, we are asking many people to tell us how often they lie.

**Table 1** Comparison of the Unweighted and Weighted Demographics of the Study Sample to U.S. Census Data and eNation Demographic Targets

|                           | <i>CPS</i> <sup>a</sup><br>(January 2007) | <i>eNation</i><br>Target | Unweighted<br>Results | Weighted<br>Results | Weighted<br>± <i>CPS</i> |

Note: *CPS* = Current Population Survey.

<sup>a</sup>Synovate weights are based on most current monthly *CPS* data at the time of study (March 2008).

<sup>b</sup>Race and Hispanic *eNation* targets are adjustments toward the U.S. Census data, not Census-based targets.

Subjects were then asked, using an open-ended format, how many times they had lied in the past 24 hours. They responded separately for lies to family members, friends, business contacts, acquaintances (“people you do not know but might see occasionally”), and total strangers; for each type of receiver, they were asked about lies in both face-to-face and mediated situations. Response categories were used as

**Figure 1** Screen shot of the Internet survey page giving a definition and description of lying.

a mnemonic device and to provide additional detail for the analysis. The results of the 10 receiver-mode combinations were aggregated. Specifically, the question was worded:

Think about where you were and what you were doing during the past 24 hours, from this time yesterday until right now. Listed below are the kinds of people you might have lied to and how you might have talked to them, either face-to-face or some other way such as in writing or by phone or over the Internet. In each of the boxes below, please write in the number of times you have lied in this type of situation. If you have not told any lies of a particular type, write in "0." In the past 24 hours, how many times have you lied?

The subjects were presented with a response grid showing the five types of people and two modes of communication. Subjects were instructed to enter a number in each box. The Internet questionnaire required a response in each of the 10 boxes before allowing the subject to continue to the next Web page. Figure 1 presents a screen shot of the lying description used in the Web survey; Figure 2 is a screen shot of the survey question. Based on the  $5 \times 2$  individual categories of responses, the row, column, and grand total frequencies (of lies per day) were aggregated for each subject.

## Results

The results of this national study are consistent with the oft-cited observation that *on average* Americans tell one to two lies per day ( $M = 1.65$  lies per day,  $SD = 4.45$ ,  $Mdn = 0$ ,  $Mode = 0$ ,  $N = 998$ ,  $Max = 53$  lies,  $95\% \text{ CI} = 1.37\text{--}1.93$ ).<sup>2</sup> But the most intriguing finding is the distribution of responses, not the mean. As Figure 3 illustrates the majority of people report telling no lies during the past 24 hours and most of the reported lies are told by few people. The 40.1% who reported lying told a total of

Figure 2 Screen shot of the Internet survey page with the question and response grid.

Figure 3 (A) The majority of Americans reported they did not lie in the past 24 hours (59.9%). (B) Percentage distribution by number of lies told; 32.2% told one to five lies and 7.9% reported telling six or more lies.

1,646 lies ( $M = 4.11$ ,  $SD = 6.26$ ,  $n = 400$ ). Of these, 22.7% of all reported lies were told by 1% of the national sample. Results indicate that one-half of all reported lies are told by just 5.3% of American adults ( $M = 15.61$ ,  $SD = 11.22$ ,  $n = 53$ ).

Figure 4 indicates that, among those who reported lying, the proportion of people who report a particular number of lies per day decreases as a function of the number of lies. Moreover, observation of this curve suggests that the decrease is a standard power function. Fitting a power function curve to these data produces

**Figure 4** Frequencies of total, face-to-face, and mediated lies are represented by similar standard power functions.

the equation  $y = 152.225 \times x^{-1.209}$  where  $x$  is the number of lies reported per day and  $y$  the frequency of people reporting a given number of lies. The function's sizeable intercept indicates that the majority of respondents who report lying do so in moderation, and the steep negative slope indicates the substantial decrease in frequency as the number of daily lies increases. Figure 4 also indicates that this pattern holds regardless of mode of communication. Although the slopes for both face-to-face lies and mediated lies are even steeper than that of the aggregated data, both retain the power law character of the total data set. Regardless of mode, most people report telling no lies and as the curve-fitting for number of lies reinforces, among those who report lying, most tell very few lies; but in each case, there are a few subjects who account for a large proportion of the lies being told.

Similarly, Figure 5 (among those telling face-to-face lies) and Figure 6 (among those telling mediated lies) indicate that lying behavior replicates the fractal character of power functions observed in other disciplines such as biological systems (Brown et al., 2002) and market segmentation (Anderson, 2008). Although each group of lies told to family members or friends or other types of message receivers represents only a small portion of the total lies, within each of the 10 mode-receiver combinations, the power function pattern is repeated. Most of the variation is among the intercepts and reflects that more lies are typically told to family members or friends than to acquaintances or total strangers.

These data do not include the number of interactions by type; therefore, it is possible that this variation is as much due to the number of opportunities for lying as it

**Figure 5** Standard power function curves fit the frequencies of face-to-face lies plotted by number of lies for all receiver types.

is that people are more likely to lie to others with whom they are familiar. Establishing the proportion of interactions involving lies may be more difficult than establishing the rate of lying for a prescribed time period. All of the diary studies to which these results are compared are flawed with regard to the interaction ratio. In order to capture as many lies as possible, DePaulo et al. (1996) specified that subjects were to record all interactions of 10 minutes or more. Subjects were told to record all lies that occurred during these interactions and, importantly, record lies occurring during shorter interactions as well. As a result, the ratio of total lies, regardless of interaction duration, to 10-minute interactions distorts the true relationship. If the number of 10-minute interactions varies across respondents or modes of communication, these comparisons may be more misleading than comparisons of the number of lies in each category during the fixed 24-hour time frame. Subsequent diary studies incorporate the lie per interaction distortion created by the DePaulo et al. methodology.

In order to consider more fully the possibility of individual differences in the propensity to lie, a multiple regression analysis was performed. Initially, a natural logarithm transformation was applied to the continuous lying measure as a means of reducing its nonnormality. Although not eliminating the nonnormality completely, this transformation had the effect of decreasing skewness by a factor of approximately 4 and kurtosis by a factor of approximately 18. To assess the impact of the demographic measures on lying, the natural logarithm transformed lying measure was regressed onto all demographic measures. Trivial predictors were dropped, the analysis was iterated, and two important, albeit modest in magnitude, predictors

**Figure 6** Standard power function curves fit the frequencies of mediated lies plotted by number of lies for all receiver types.

emerged ( $R = .21, F(2, 979) = 22.82, p < .001$ ). First, age was an important predictor ( $\beta = -.18, t(979) = -5.71, p < .001$ ), and the effect was such that a decrease in lying was associated with increasing age. Second, race (Caucasian vs. other) was an important predictor ( $\beta = -.09, t(979) = -2.99, p = .003$ ), and the effect was such that Caucasians reported lying less than other racial groups. This analysis was replicated with the dichotomous not lie/lie measure, with the same two important predictors emerging in the subsequent logistic regression analysis.

No sex differences were observed when controlling for other demographic predictors. Bivariate analysis showed that the overall rate of lying by men ( $M = 1.93, SD = 4.81, n = 482$ ) and women ( $M = 1.39, SD = 4.08, n = 516$ ) is directionally but not significantly different when using conventional criteria for statistical significance ( $t(996) = 1.89, p = .059/\text{ns}$ , two-tailed,  $d = 0.12$ ).<sup>3</sup> This apparent gender difference is in the opposite direction observed by DePaulo et al. (1996) but is consistent with the finding that women find lying less acceptable than men (Levine, McCornack, & Avery, 1992).

### Discussion

The results of this national study are consistent with the DePaulo et al. (1996) diary study and suggest that *on average* Americans lie once or twice a day. However, the important findings are that many people do not lie on a given day, the majority of lies are told by a few prolific liars, and because the distribution is highly skewed, the mean number of lies per day is misleading. This pattern is consistent across modes of

communication and varies little on the basis of who is being lied to. Examination of individual differences suggests some variation but in most cases the differences are small.

The representativeness of online panel data is debatable. Use of poststratification (such as employed by Synovate) and propensity (likelihood of response) weighting schemes are the usual solutions to matching panel samples to the population. In general, the use of a large number of small and internally homogeneous strata will enhance the proportional fit of the sample to the population. However, non-coverage and self-selection can create sampling problems in Web-based research that weighting does not solve (Loosveldt & Sonck, 2008). These representativeness issues are of particular concern when the measured values are correlated with the underlying reasons for the selection bias. However, when measuring socially undesirable behavior, assessment of representativeness is confounded. Loosveldt and Sonck obtained measures for validation of questions influenced by social desirability using face-to-face interviews; this introduces potential mode effects. Even with the selection problem, the social distance advantage of the Internet may actually produce better data. Birnbaum (2004) provides an argument for representativeness when the results are homogeneous across strata. Because selection bias tends to vary across the levels of a stratified sample, small individual differences for a measure across the stratification variables is evidence that the aggregate finding transcends the sampling issues and is indicative that the sample result is representative of the phenomenon in the population as a whole. In Study 1, confidence in representativeness is enhanced by the homogeneity of the results across strata, and convergent validity is subsequently established by consistency with the results in Studies 2 and 3, and by the advantage of the Internet for creating social distance in the measurement of a sensitive topic.

Although the findings were generally homogenous across the sample of adult Americans, some small demographic differences were apparent. Notably, age and race/ethnicity account for small but statistically significant variation. Further, the difference between reports of lying by men and women approached statistical significance. These findings may have theoretical, social, and cultural implications.

Perhaps the most interesting individual difference is the negative association between lying and age. Lying is acquired by children in early childhood and the ability to lie is correlated with the acquisition of perspective-taking, theory of mind, and communication skills (Vasek, 1986; see Knapp, 2008, pp. 91–116 for a summary discussion of lying and development). As the child reaches adolescence, lying skill is perfected, but lying declines in acceptance in early adulthood (Jensen et al., 2004). The difference between rates of lies reported by the DePaulo et al. (1996) student and (adult) community samples suggests that maturity tempers the usage of lying as a strategy for goal attainment, and the current findings of the national data in Study 1 are consistent with the claim that the lying declines with age.

With regard to the finding that Caucasians report fewer lies than those of other ethnic or racial groups, it would be irresponsible to simply conclude that White people are more honest in general than those of other races. Research on race and

deception is limited, and more research is required to make sense of this finding. The current study also found a marginally significant trend toward men reporting more lies than women. Some studies suggest men lie more than woman while others suggest the opposite (e.g., DePaulo et al., 1996; Levine et al., 1992). Other research finds that sex differences vary by the topic of the lie (Haselton, Buss, Oubaid, & Angleitner, 2005).

## Study 2

The results of Study 1 replicate, with a large and nationally representative sample, the often repeated conclusion that people lie, on average, once or twice per day. The results also document that the distribution of lies per day is substantially skewed. Most reported lies were told by a few prolific liars.

These findings have important implications. Most importantly, the nature of the distribution makes conclusions drawn from sample means misleading. Although the mean lies per day reported in the literature appear reflective of aggregate reality, the mean as a central tendency does not reflect the lying behavior of the typical person. Instead, most people reported telling no lies at all on a given day, with the median and mode both being zero. We are not the first to note this shape for the lie frequency distribution. A similar pattern, with many telling a few lies and a few telling most of the lies, was reported by Feldman, Forrest, and Happ (2002) in a laboratory study on self-presentation. But in their analysis of the data, the skew was treated as a methodological limitation rather than as a finding. The clarity of the results observed in the national study raises a question of whether or not this pattern existed in previous studies reporting lying frequency.

## Method

The raw data were obtained from the student phase of the DePaulo et al. (1996) study and from both phases of the George and Robb (2008) study. A distribution of lie frequency was partially reconstructed from the results reported by Feldman et al. (2002). The shape of each of the four distributions (excluding those reporting no lies) is examined, and the resulting distributions are compared with the overall results from the national survey. Data from the DePaulo et al. community sample and Hancock et al. (2004) studies were not available.

## Results

### *DePaulo et al. (1996)*

Of the 77 students sampled by DePaulo et al., 76 reported telling at least one lie over the period of 1 week ( $M_{\text{week}} = 13.74$ ,  $SD_{\text{week}} = 11.40$ ; this is equivalent to  $M_{\text{day}} = 1.96$ ,  $SD_{\text{day}} = 1.63$ ); the total number of lies told was 1,058; and the most lies told by one person was 46 (equivalent to 6.6 lies per day). Curve-fitting yields a power function for these data of  $y = 5.366 \times x^{-0.290}$  ( $n = 76$ ,  $r^2 = .289$ ). This function has a poor fit; however, no equation provided a fit better than  $r^2 = .350$ . Even so, the

data exhibit the overall distributional properties of a few lies told by most of the subjects and most of the lies told by a few liars. Of the total students in this study, 66.2% told the equivalent of two lies per day or less. Conversely, the seven most frequent liars (9.2% of the sample) told more than the equivalent of five lies per day, or 26.2% of all lies reported. Although raw data for the community sample are not available, DePaulo et al. reported 64 of 70 subjects told 477 lies with  $M_{\text{week}} = 6.79$  ( $SD_{\text{week}} = 6.86$ ) and  $Mdn_{\text{week}} = 4.5$ ; these measures suggest a positive skew similar to that observed with the student sample.

*George and Robb (2008)*

Two studies were conducted following the diary methodology used by DePaulo et al. (1996) and Hancock et al. (2004). The objective of the two studies was to examine variations in deceptive behavior by media use. A key difference between these studies and the prior diary studies was the use of PDAs instead of paper and pencil to record interactions and lies. In the first study, George and Robb used the 10-minute minimum time established in the prior diary studies to define an interaction; in the second study, the minimum interaction time was reduced to 5 minutes. In both studies, subjects were instructed to record lies even when the interaction was shorter than the prescribed time.

Results of this research are notably different from the prior diary studies. In each study, the mean number of lies was small. In the first study, 24 of 25 subjects reported lying over the period of a week ( $M_{\text{week}} = 4.16$ ,  $SD_{\text{week}} = 2.59$ ; this is equivalent to  $M_{\text{day}} = 0.59$ ,  $SD_{\text{day}} = 0.37$ ;  $Mdn = 4$ ); the total number of lies told was 104; and the most lies told by one individual was 11 (the equivalent of 1.6 lies per day). Despite the low average, only one subject who reported lying told fewer than two lies; consequently, a power function could not be fit to the distribution (if this individual is eliminated a power function with a modest  $r^2 = .758$  can be fit to the remaining data). Even with this poor fit, the distributional properties of the study demonstrated a positive skew similar to the national survey and the DePaulo et al. (1996) diary study. Half of the subjects (48% of the sample) told just 25% of the lies while the three subjects (12%) reporting the most lies told 26.9% of the lies.

In George and Robb's (2008) second study, the length of interaction was shortened in order to encourage more reporting. As a result, 23 of 24 subjects reported lying over the period of a week and the lying frequency increased from the first study ( $M_{\text{week}} = 6.33$ ,  $SD_{\text{week}} = 3.78$ ; this is equivalent to  $M_{\text{day}} = 0.90$ ,  $SD_{\text{day}} = 0.54$ ;  $Mdn = 5$ ). The total number of lies reported was 152 and the most lies told by one individual was 14 (the equivalent of two lies per day). Similar to the first study, and despite the overall low number of lies told, those reporting lies told a minimum of two lies; consequently, a power function could not be fit to the data. Nonetheless, the positive skew is again apparent in the pattern of responses. Just three subjects (12.5% of the sample) told 40 of 152 lies (26.3% of the total).

Although addressing a much shorter time frame in an experimental setting, Feldman et al. (2002) observe the same distinct skew pattern in their lying data as was observed in the daily national study and the weekly student diary studies. This study examined lying as a component of self-presentation; a sample of 121 students was divided into two induction groups and an experimental control. Across all subjects, a total of 211 lies were analyzed with a mean of 1.75 lies per subject and 2.92 lies per subject who lied.<sup>4</sup> Of the 121 subjects, 49 told no lies (40.5%), 23 told one lie (19.0%), and 18 told two lies (14.9%). The maximum number of lies was 12. Thus, 74.4% of the total sample accounted for only 28% of the lies told. The remaining 31 subjects (25.6%) told 3–12 lies, accounting for 72% of the lies ( $M = 4.9$  lies per subject).

When prior research reporting the frequency of lies is reexamined, results show the small diary samples, the experimental self-presentation study, and our large, national self-report survey have similarly skewed distributions. In all cases, the infrequent liars are a large part of the sample and account for a disproportionately small share of the lies reported. Conversely, each study includes a small number of individuals who account for a disproportionately large share of the lies.

### **Study 3**

Several issues are of concern despite the consistency of the findings across studies and the face validity obtained by reanalysis of prior studies reporting lie frequency. Primarily, these concerns have to do with the accuracy of the study findings using the survey approach to obtaining self-report data. Further, the apparent discrepancy between the numbers of nonliars when the time frame is 1 day versus the number when the time frame is 1 week needs to be resolved. For these reasons, the national survey was replicated using student samples and additional measures.

#### **Accuracy of reporting lies**

An obvious concern with self-report, mass survey research is accuracy of reporting. Bias in the national study data, if it exists, would likely manifest itself as underreporting. Given the pervasive cultural prohibitions against lying, self-presentation motives favor under- rather than overreporting. Methodological research on other sensitive topics such as drinking (Lemmens, Tan, & Knibbe, 1992) and sexual behavior (Ramjee, Weber, & Morar, 1999) indicates that diary studies produce higher mean scores than self-report questionnaires. The diary method used by DePaulo et al. (1996) is expected to be less susceptible to underreporting bias even though the study had the added limitations of a smaller and nonrepresentative sample. Because the mean number of lies per day in the national survey data was greater than the mean observed in the diary research, concern that the national study may be underreporting due to the use of the self-report questionnaire method is not consistent with results of most comparisons of survey research to an alternative diary method. Thus, the

observed frequency of lying reported is not likely attributable solely to the survey methodology used to collect the national study data.

Nonetheless, a survey of lying behavior invites the question: “How do you know the subjects are not lying?” One answer resides in the methods used to address sensitive questions. Tourangeau and Yan (2007) identify four techniques for asking sensitive questions that might contribute to improved prevalence measurement: Use of self-administered rather than interviewer-administered questions, forgiving wording, randomized response techniques (RRT), and use of the bogus pipeline (BPL) approach. The national survey of lying was conducted as a self-administered study and used a forgiving wording preamble. The meta-analysis by Tourangeau and Yan (2007) provides clear evidence that self-administration yields more behavioral reporting for sensitive topics than does interviewer-administration. There is limited evidence that forgiving wording may also be helpful. Catania et al. (1996) found increased reporting of sexual activity but a series of experiments by Holtgraves, Eck, and Lasky (1997) suggest that forgiving wording is more likely to improve attitudinal responses than behavioral reporting.

A second answer can be obtained through the use of additional measures in order to assess the social desirability bias (SDB) in the self-report measures (Fisher & Katz, 2000). This is sometimes done directly by obtaining measures of SDB using a scale of SDB traits (Crowne & Marlowe, 1960; Reynolds, 1982) and adjusting for the subjects’ level of bias. Alternatively, Fisher and Katz suggest the validity of reports of a socially undesirable behavior such as lying can be assessed indirectly, for example, by comparing the self-report of that behavior to subjects’ estimates of the extent of that behavior in others. Subjects in Study 3 were asked to report the total number of times others had lied to them in the past 24 hours.

#### **Minimum observable differences**

A second key issue raised by the results of the national study is the minimum observable difference of one lie per day. Those who lie but do so less than once a day may be recorded as having told no lies. Because the frequency of lies is typically reported as the rate of lying in a fixed interval of time (i.e., one to two lies per day), expanding the duration in which the behavior can be observed is likely to increase the overall reported incidence of the behavior; measures taken over a longer period and converted to a daily rate will also increase precision. In order to observe those who lie once a week or once a month or even less frequently, it is necessary to use a wider time aperture. In the student sample of the DePaulo et al. (1996) study, 30% of diaries recorded six or fewer lies per week (less than once per day). If the number of lies told in a week is evenly distributed across the days of the week (and there is no reason to believe an even distribution is a good assumption), we might expect that as many as 17% (those reporting four, five, or six lies in a week) have an above average likelihood of being included as liars in a 1-day study. But the other 13% (reporting one, two, or three lies in a week) would be more likely to report not lying on the survey day. Identifying infrequent liars by repeating the daily survey on 2 or

more days with the same sample, or by asking those who report no lies to identify other times when they had told a lie, we would expect to narrow substantially the gap between the national study observation that 40% told a lie on one given day and the DePaulo et al. result that 95% of subjects (both studies combined) reported at least one lie over the period of a week.

## **Method**

### *Participants and design*

Students were recruited from communication, advertising, and marketing classes at two large universities in the Midwestern United States. Of the 229 subjects, two failed to provide complete information regarding the number of lies told and two provided answers that were determined to be statistical outliers using a discordancy test. These subjects were excluded from the analysis. Of the remaining 225 respondents, 140 were female (62.2%) and 85 were male (37.8%). Participation was voluntary.

The primary purpose of this study was to cross-validate the results of the national study using a separate sample. A nonexperimental survey design similar to that of the national study was used in order to obtain comparable descriptive measures for the incidence of lying in the student sample. Results from this survey are compared with those of Study 1 and the reanalysis of prior studies in Study 2.

### *Procedures and measures*

The study was administered in five separate classroom settings using a paper questionnaire. The introduction and frequency of lies question were identical to that of the online survey used with the national sample except that students could leave parts of the  $5 \times 2$  grid blank (the online survey forced subjects to place zeroes in all cells for which no lies were told before they could continue with the questionnaire). Blank cells were coded as zero lies. In addition, those subjects who reported telling no lies in the past 24 hours were asked a follow-up closed-ended question regarding when they last told a lie. Response categories included, “more than 24 hours ago but within the last 2 days,” “more than 2 days ago but within the last week,” “more than a week ago but within the last month,” “more than a month ago,” and “never.” Subjects were asked how many lies they had been told by others in the past 24 hours and what percentage of the U.S. adult population lies on a given day. One group of subjects was asked about the difficulty of the lie reporting task.

## **Results**

The pattern of lie frequency for the total student sample is consistent with the distribution of lies for the national survey using the same frequency measure. The data fit a power function of  $y = 53.891 \times x^{-1.012}$  with a goodness-of-fit of  $r^2 = .894$ . The pattern of many telling few lies versus a few telling many lies is reproduced in the student sample frequencies. Of the total subjects in the student sample, 68.4% told one, two, or no lies (accounting for 24.5% of 526 total lies); conversely, the 13 most prolific liars (5.8% of the total sample) told 22.4% of the lies. On the basis of the relationship

of the means in the DePaulo et al. (1996) student and community diary studies, we expected the mean of the student survey to be higher than the mean of the national adult sample. Results from the student sample ( $M = 2.34$  lies per day,  $SD = 2.94$ ,  $Mdn = 1$ ,  $Mode = 0$ ,  $N = 225$ ,  $Max = 21$  lies, 95% CI = 1.95–2.72) indicate higher frequency than in the national survey (nonoverlapping 95% confidence intervals;  $t(1221) = 2.62$ ,  $p < .01$ ,  $d = 0.18$ ).

Those subjects who reported telling no lies in the past 24 hours (28.9%) were asked the follow-up question regarding when they last told a lie. Combining those who indicated their most recent lie was within the past week (though not in the past 24 hours) with those who reported at least one lie in the past 24 hours, a total of 92.4% reported telling a lie in the past week (204 of 221 subjects; 4 did not answer the follow-up question). This result is reasonably consistent with the DePaulo et al. (1996) result of 95%.

Since there is a legitimate concern about SDB in the self-report of lying, a check on the subjects' reported rate of lying (lies per day) was obtained by asking subjects in the student sample how many times they believe they were lied to by others in the past 24 hours. Subjects reported that others told an average of 2.79 lies in the past 24 hours ( $SD = 2.82$ ,  $N = 198$ ). Although 28.9% reported telling no lies, 17.2% reported not being lied to by others. Own lies ( $M = 2.34$ ,  $SD = 2.94$ ) are significantly lower than others' lies; the paired sample  $t(197) = 2.18$ ,  $p < .05$ . Despite this significant difference, the distribution of others' lies is strikingly similar to that of own lies following the long-tail pattern observed in the self-report of lies (the power function for others' lies is  $y = 44.552 \times x^{-0.790}$  with a modest goodness-of-fit of  $r^2 = .700$ ). It is important to note that individual subject's reports of others' lies did not mimic their self-report of lying. The correlation of the two measures is a meager  $r = .073$  ( $p = .152$ , *ns*).

Participants were also asked what proportion of the U.S. adult population (18 years or older) told at least one lie on any given day. The mean estimate is 75.8% ( $SD = 21.7$ ). The proportion of students (who are a subsegment of the adult population) telling at least one lie in the past 24 hours is 71.1% (CI =  $\pm 5.9\%$  points). Although not directly comparable due to the different ways in which the proportions were derived, in both instances one percentage falls within the confidence interval of the other, suggesting that the two proportions would not be significantly different.

### Discussion

The results of Study 3 fit a power function similar to that of the national survey and further indicated that, based on self-reports of lying behavior, most people tell few or no lies in a given day but a few prolific liars tell a disproportionately large share of the daily lies. Survey results, diary studies, and the distribution of lies in an experimental setting share this pattern, and the consistency of results provides strong evidence that the frequency of lying has a strong positive skew. The similarity of subjects' estimates of others' lies and the distribution of number of lies told provides convergent validity for the self-report measure of lying.

With regard to the accuracy of mean prevalence figures, Study 3 provides mixed results. The mean reported by this student sample is 2.34 lies per day and expands the range of responses across all studies to 0.59–2.34 lies per day. The mean for the student survey is significantly higher than the mean of the national survey of American adults. This is similar to the relationship observed by DePaulo et al. (1996) for their student and community samples. Consistent with the Study 1 finding that younger people tend to lie more than older people, the predominantly young student sample has a higher frequency of lying. Two measures were obtained to assess the validity of the reported lying frequency. One measure estimated the proportion of the population that lies on a given day; the result of 75.8% is similar to the Study 3 result showing that 71.1% of the subjects told at least one lie in the past 24 hours. However, an estimate of others' lies to the subjects ( $M = 2.79$ ) is significantly higher than the average of the subjects' own lies. Either the subjects truly believe that other people lie more than they do or the subjects are slightly but systematically underestimating their own lying behavior.

Regardless, the difference is one of degree and not magnitude, and the relevant finding is the consistent skew of the distribution and not the average number of lies told. In fact, the mean of a long-tail (power) distribution is in part a function of sample size. As the sample size increases, the probability of rare but legitimate extreme values that are not statistical outliers being reported also increases. In Study 1, the maximum number of lies by one person was 46 ( $N = 998$ ). Study 3 consisted of five subsamples (separate classroom administrations of the survey) and the maximum number of lies told was closely associated with sample size. In the largest subgroup ( $n = 118$ ), the maximum number of lies was 21. In the next largest group ( $n = 31$ ), the most lies told was 12. In the three smallest subsamples ( $n = 26, 25$ , and  $25$ , respectively), the most lies told by one person were 10, 8, and 6.

A question related to accuracy may be raised with regard to the difficulty of the task (since it might be expected that a more difficult task would produce increased variance). We note that researchers familiar with the topic of deception tend to struggle more with the question asked in the self-administered survey than do naive subjects. Those familiar with the deception literature wrestle with the explication of lying and, perhaps because of this cognitive effort, their own ability to recall precisely over a 24-hour period. Naive subjects seem to have no such problem. As a check, 25 students in one Study 3 subsample completed the recall of lies task and were subsequently asked to rate the difficulty of answering the question. On a 1–10 scale (1 = not at all difficult; 10 = extremely difficult), the subjects reported  $M = 3.48$  ( $SD = 3.03$ ) with the  $Mdn = 2$  and the Mode = 1. Most subjects seemed to feel that they were able to complete the task with little difficulty. During a verbal debriefing of this subject group, subjects reiterated that most had made an earnest effort to estimate the number of times they had lied and most felt the task was not difficult.

Finally, Study 3 appears to have resolved the discrepancy in the proportion of nonliars reported in the daily survey and weekly diary results. All of the diary studies report that more than 90% of the subjects told at least one lie in the period of 1

week. However, many of those subjects lie at a rate that translates to less than one lie per day. When Study 3 subjects who did not report lying in the 24 hours preceding the survey were asked when they last told a lie, results indicate that most did lie in the previous week. Therefore, the apparent discrepancy is due to the precision of the question being asked. The daily questions do not allow for fractional responses, whereas the conversion of weekly data to daily data inherently creates fractional reporting. When the precision issue is accounted for by additional measurement, the discrepancy disappears.

### General discussion

The results of Study 1 reproduce with a large, national sample the conclusion that people lie, on average (arithmetic mean), once or twice per day. More importantly, the results document that the distribution of self-reported lies per day is substantially skewed. Most people report telling few or no lies on a given day and most reported lies are told by a few prolific liars. The reanalyses in Study 2 and the replication of the survey methodology in Study 3 provide strong evidence in support of this finding. All the data reported here are consistent with the claim that most lies are told by a few prolific liars.

The highly skewed, long-tail distribution that results from reports of lying may be emblematic of a larger class of behaviors. Although much of what we measure and observe relies on the principle of randomness and results in the well-known bell-shaped curve of observations distributed around a central tendency for a phenomenon, scientists continue to find new evidence for a self-organizing principle in nature that produces distributions that are scale-free, or lacking in a characteristic tendency (Barabási, 2003; Barabási & Albert, 1999). This principle is found in the examination of atomic structure, biological systems, economic theory (the Pereto Law or “80/20 Rule”), and the emergence of nodes on the Internet. The latter describes a pattern consisting of a few very large nodes that are connected with extremely high frequency (e.g., Google, eBay, and Amazon.com) that are surrounded by over 100 million smaller and, in many cases isolated, Websites. But it is the human tendency to search, use, and link to these few extreme large sites while ignoring so many others that creates this apparent scale-free pattern in the first place. It may be less the case that lying is some unique form of communicative behavior that divides people into those who do it (with vigor) and those who do not than an indicator that we need to reexamine a broad range of social and symbolic behaviors, look for scale-free distributions, and consider broadly the implications for all forms of communication research.

Our finding with regard to the distribution of reported lies has specific implications for the conclusions drawn from deception detection accuracy experiments. A meta-analysis shows that people do only slightly better than chance (54%) when distinguishing between truths and lies (Bond & DePaulo, 2006). In the experiments

cited by Bond and DePaulo, the deception base rate is almost always 50% and subjects are typically truth-biased. Truth bias leads to the veracity effect, meaning that accuracy is higher for detecting honest messages than for detecting lies (Levine, Park, & McCornack, 1999). As a consequence, honesty base rates impact accuracy such that people are increasingly accurate as the proportion of truthful to deceptive messages increases (Levine, Kim, Park, & Hughes, 2006). The finding that most people are honest most of the time suggests that experiments employing nonrepresentative base rates (i.e., a lower proportion of truths to lies than is typical of everyday interactions) will underestimate accuracy. Findings from this general population study indicate that truth bias may be functional. Since self-report data suggest most people do not lie or tell very few lies in the course of a typical day, it is reasonable for people to believe others (that is, to be truth-biased) most of time.

However, although laboratory deception detection experiments may underestimate overall accuracy due to nonrepresentative base rates, lie detection rates may be overestimated. The current findings suggest substantial individual differences for truth telling (or lying) with an honest majority and a few prolific liars. Bond and DePaulo (2008) report substantial variation in both people's demeanor and people's ability to lie. People's ability to lie successfully likely impacts how often they lie (Kashy & DePaulo, 1996). We speculate that the prolific liars are likely those people with especially honest demeanor and that unusually transparent liars avoid lying. If most lies outside the laboratory are told by people who are usually believed, lie detection rates would be lower than those observed in randomized experiments.

One caution relates to Rozin's (2001) concern for achieving "context- and culture-sensitive scientific social psychology." The large sample of American adults used in the current research is more representative and allows greater generalizability than previous studies using students and other convenience samples. Nevertheless, caution should be taken before assuming that these results will hold for other cultures, individuals under 18 years of age, or subsets of the population with characteristics or beliefs that are sharply discrepant from the norm. Anecdotal evidence suggests that base rates may well vary across cultures and studies of lying involving young children and adolescents show considerable variation in the ways lying occurs (Knapp, 2008). Criminals, political extremists, and those at the far ends of the socioeconomic spectrum may well behave differently than the vast majority of the American population. The domain of deception research would benefit from cross-cultural, subcultural, and cross-generational examination of the prevalence and distribution of lying behavior.

## **Conclusion**

Over time, most Americans probably lie at least occasionally. But the inference of pervasive daily lying, drawn from the statistical average of one to two lies per day, and reinforced by media coverage of corporate deception and political malfeasance, as well as pop culture portrayals of deception detectors, belies the basic honesty

present in most people's everyday communication. Self-report data for the U.S. adult population show the average rate of lying is around 1.65 lies per day; but the data are not normally distributed. On any given day, the majority of lies are told by a small portion of the population, and nearly 6 out of 10 Americans claim to have told no lies at all. As researchers continue to examine the nature of lying and look for ways to detect deception effectively, both the theories of deception, and the methods used to test those theories, necessarily must take into account that veracity is not a constant across the population and that the propensity to lie can be an important moderator.

### Notes

- 1 Synovate, Inc. (Chicago) conducts marketing research and strategic studies for business, industry, and government agencies. White papers on the omnibus methodology are available at [www.synovate.com](http://www.synovate.com). The omnibus panel was surveyed on April 30, 2008.
- 2 Two subjects, one with an extreme value of 134 lies (20.8 standard deviations above the mean of 1.80 lies) and a corresponding subject with no lies, were eliminated from the sample by  $\alpha$ -trimming. Using procedures outlined by Barnett and Lewis (1978), a discordancy test appropriate for gamma distributions was applied to the data. Even though the potential for extreme values is inherent in the tail of the power function, the most extreme value recorded in these data is well beyond the limits of statistical probability.
- 3 The application of a  $t$ -test for establishing the significance of differences for nonnormal distributions is problematic. Nonetheless, in those situations where the shapes of the distributions are similar, the sample sizes are similar, and the samples are sufficiently large the  $t$ -test will provide an acceptable test of significance even though the assumption of normality has been violated (Johnson, 1978). Although most of the small student sample studies fail to meet all of these conditions, the power distributions in this large-scale national study replicate for most subsamples and do so with large enough samples to allow for robust statistical testing. An alternative is to make the nonparametric assumption and apply difference testing accordingly. Calculating chi-square for age (under 45 years old vs. 45 years and older) and lying (did vs. did not lie) yields  $\chi^2(1, N = 998) = 36.59, p < .001$ ; this leads to a conclusion similar to the one reported in the text, specifically that younger people are more likely to lie than older people. Calculating chi-square for gender and lying yields  $\chi^2(1, N = 998) = 2.84, p < .092$ ; again the result is consistent with the reported  $t$ -test showing that men are directionally but not significantly more likely to lie than are women.
- 4 Despite including the induction groups, using a student sample, and being constrained to only those who told lies, the mean of 2.92 lies has been misinterpreted in the media (online program description, *About Lie to Me*, 2009, <http://www.fox.com/lietome/about>) and in scholarly work as claiming "in the course of a 10-minute interaction . . . the average person tells two to three lies" (Harrington, 2009, p. 4).
